• In order to verify the safety of the geological high-level radioactive waste disposal, IRSN has undertaken the SEALEX research project to control the long-term performance of swelling clay-based sealing systems. Compacted bentonite-sand mixture is one of the most appropriate sealing material studied in this project because of its low permeability and good swelling capacity.

 Once installed, this material will be in contact with the host-rock pore water and start swelling to close all the gaps in the system (internal pores, rock fractures and technological voids) and then, swelling pressure develops. In parallel with the in-situ SEALEX project, laboratory experiments are performed to investigate the sealing properties under this complex hydro-mechanical condition taking into consideration the effect of technological voids.

# Two Approaches

- No effect of technological void on the swelling pressure
- The final dry density controls the swelling pressure

# Obvious effect of technological void

- The hydraulic conductivities with technological void are higher than those determined in constant volume condition
- That evidences the preferential pathway of water in the zone of technological void (filling material is more permeable)

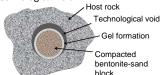

# 1E-12 T 1E-14 1E-15 Dry density of mixture (Mg/m<sup>3</sup> O With technological void (Darcy's law - inflow) Constant volume (Darcy's law - inflow, Gatabin 2008) stant volume (Darcy's law - outflow, Gatabin 2008)

- Objective:
- Investigate the recovery capacity of compacted bentonite-sand mixture when considering a 14% of technological void
- Provide useful information about the effectiveness of field design
- Methodology: Design a small scale (1/10) of the in situ SEALEX experiment model test

# (1) Initial saturation (2) Recovery of void (3) Confinement

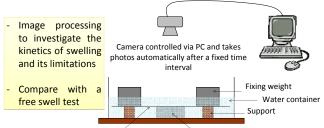

Blocks start being saturated from their surface and swell forming a loose gel that will grow to fill the technological void.

The state of the gel formation is changing with time in parallel with a constant evolution of the hydro-mechanical conditions.

A better understanding of this changing gel formation is essential in assessing the performance of the total sealing structure.

Follow the swelling of a block immersed in water by time-lapse photography

Transparent plate Bentonite-sand block

# Compacted state Compacted block water Initial State

- Loose gel Final State
- different state than the central material
  - The filling material is a loose gel which state is changing with time

The annular void have been

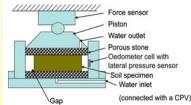

has

filled in 2h30min The filling material

Generation of lateral swelling pressure

(Annular void: 50%)

- From a mechanical point of view, due to this non homogeneity, the swelling pressure generated radially will be compared to the axial one
- Investigation of an anisotropic behavior
