HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

H2020 projects and EU research needs for Nature-Based adaptation Solutions

2 Abstract

1

3 This paper investigates the documentation produced by 21 Horizon 2020 (H2020) projects for the use of Nature Based Solutions (NBS) for climate change adaptation (NBaS). Accordingly, an updated state-of-4 5 the-art on current knowledge and its limits is presented. Findings are then capitalized on for highlighting 6 research needs. The main objective of this study is to inform future orientations on NBaS research. 7 Accordingly, it can be considered as an effort to complement the 2021 European strategy for climate change 8 adaptation, under which NBaS is listed as one of the three cross-cutting priorities. The obtained results reflect actual outcomes from completed projects, while ongoing projects provided a substantial amount of 9 relevant knowledge. From the exhaustive knowledge-research need inventory, one of the most significant 10 identified gaps was the need for developing further the fundamental scientific basis behind these solutions. 11 as the concept favors its practical nature and places less emphasis on its scientific counterpart. 12

13 Keywords: nature-based solutions, adaptation, NBaS, Horizon 2020

14 **1. Introduction**

The apex position of Climate Change Adaptation (CCA) and Nature-Based Solutions (NBS) in European priority agendas underlines the importance of these concepts for Europe. CCA has been a central interest for the EU since 2013 with the EU Adaptation Strategy (European Commission, 2013), while NBS as a concept, was coined at the European level. NBS are solutions that make use of ecosystems for responding to societal challenges (IUCN French Committee, 2016). First mentions of the concept (in strict terms) appeared in 2008 by the World Bank (Hanson et al., 2020). Since then, the concept has increasingly

expanded and has attracted considerable scientific attention (Castellanos et al. 2020).

22 The European Commission (2015) defines NBS as: "Solutions that are inspired and supported by nature, 23 which are cost-effective, simultaneously provide environmental, social and economic benefits and help 24 build resilience. Such solutions bring more, and more diverse, nature and natural features and processes into cities, landscapes and seascapes, through locally adapted, resource-efficient and systemic 25 26 interventions". NBS are particularly sought for their capacity to balance trade-offs between ecosystemic 27 conservation, social needs and economic growth (Al Sayah et al., 2021). Cohen-Shacham et al. (2016) 28 consider NBS as an umbrella concept that includes: (i) ecosystem restoration approaches (e.g. ecological restoration and engineering); (ii) issue-specific ecosystem-related approaches (e.g. ecosystem-based 29 adaptation/mitigation, climate adaptation services and ecosystem-based disaster risk reduction); (iii) 30 infrastructure-related approaches (e.g. natural and green infrastructure); (iv) ecosystem-based management 31 32 approaches (e.g. integrated water resources and coastal zone management); and (v) ecosystem protection 33 approaches (e.g. area-based conservation such as protected area management). Examples of NBS 34 applications are quite common around the world and range from minimal interventions (Type 1 NBS), to 35 minor ecosystem management approaches (Type 2 NBS), and extensive management/creation of ecosystems (Type 3) (Eggermont et al., 2015). Examples of minimal interventions are protected areas such 36 as the Wet Tropics World Heritage Area of Australia, where wetlands and mangroves are used for reducing 37 38 the risks of cyclones and coastal hazards (IUCN, 2014). Agroecology and agroforestry are considered as 39 applications of regulated management approaches (Hotelier-Rous et al., 2020), while green roofs [ref.

40 Versini et al. (2015)] are examples of extensive ecosystem management/creation.

41 From the European Commission's definition, the belief of Europe that long-term economic competitiveness

42 and security depend on the sustainable use of natural resources is apparent, hence its interest in NBS (Maes

43 and Jacobs, 2017). Nonetheless, climate change is one of the major hurdles that are preventing a smooth

transition towards Europe's above-mentioned belief (Castellanos et al., 2020). For this purpose, Europe has

45 set a path to harness the potential of NBS for CCA (Li et al., 2021). The occurrence of the term "adaptation"

46 within the EU's definition of NBS, in the seventh criterion for NBS of the International Union for

47 Conservation of Nature (IUCN), and as one of the seven societal challenges NBS respond to strongly 48 emphasized the NBS-CCA nexus (IUCN, 2020). The seventh IUCN criteria "NBS are managed adaptively, 49 based on evidence" takes part of eight criteria set by the IUCN (2020) for a solution to be considered as a 50 NBS [refer to IUCN (2020) for more details]. The seven above-mentioned challenges are climate change 51 mitigation and adaptation, disaster risk reduction, economic and social development, human health, food 52 security, water security and environmental degradation/biodiversity loss (IUCN, 2020).

53 In this vein, NBS for climate change adaptation (henceforth referred to as Nature-Based adaptation 54 Solutions NBaS) have gained prominence both in scientific literature (IUCN French Committee, 2019) and 55 in practical applications, particularly in Europe (Seddon et al., 2019). More recently, NBaS were defined as one of the three cross-cutting priorities in the EU's 2021 strategy on CCA (European Commission, 56 2021a). Accordingly, the strong NBaS background of Europe is pivotal to exploit for studying the evolution 57 58 of these solutions. At the French scale, NBaS are trusted to be the way forward for leveraging the second 59 national climate change adaptation plan. It is under this context that the LIFE ARTISAN (Achieving 60 Resiliency by Triggering Implementation of nature-based Solutions for climate Adaptation at a National scale) project aims to promote the implementation of NBaS throughout the French (metropolitan and 61 overseas) territory (www.life-artisan.fr). 62

63 With a favorable political context and a very receptive social fabric (Maes and Jacobs, 2017), the European Commission (EC) placed significant efforts to deepen knowledge on NBS-NBaS. Perhaps one of the most 64 65 ample translations of this interest is the integration of NBS into the Horizon 2020 R&I (H2020) program. 66 Accordingly, the latter is one of the most suitable platforms to explore as it reflects the role of the EC in research and innovation on NBS, in the allocation of funds for NBS, and in the production of tools, 67 68 databases and scientific contributions. Knowing that NBS and NBaS are based on ecosystems and their 69 services (Potschin et al., 2016), the interest of the EU in the latter increased even more after the COVID-19 pandemic. Accordingly, the EU is one of several parties developing programs that integrate natural 70 solutions (thereby NBS) into post-COVID plans as nature-positive stimulus packages (Armstrong, 2021; 71 72 GEF Secretariat, 2020). On a global scale, the EU's post-COVID19 recovery package is the most eco-73 friendly, with 37 per cent of the planned 750 billion euros directed towards green initiatives (Bayat-Renoux 74 et al., 2020). To this end, the EU is planning for an ambitious 2030 biodiversity strategy that aims to 75 transform minimum 30 percent of Europe's lands and sea into protected areas (even partially) to ensure 76 healthy societies via healthy ecosystems (GEF Secretariat, 2020).

77 Despite the strong momentum behind the concept and the high expectations, NBaS are not as simple as 78 expected. Since they encompass both CCA and NBS, NBaS inherently carry the difficulties and 79 complexities of both their components. In terms of CCA, the composite nature of climate change and its 80 uncertainties are particularly relevant (UNFCCC, 2020). In this vein, the absence of decisive measurable 81 metrics, thresholds, and proof of risk reduction at both the short (i.e. pre-2050) and long-terms (i.e. post-2050 and climatic cycle scale) are major hurdles to overcome (UNEP, 2021). Even if the mentioned 82 challenges are surpassed, the difficulty of understanding how adaptation functions and what its implications 83 for resilience are still persists (IUCN, 2010). In terms of NBS, inconclusive evidence on their performance 84 (Chausson et al., 2020), the uncertain behavior of ecosystems and their components under changing 85 climates (Weiskopf et al., 2020), the questionable quantification of tipping points and thresholds (Groffman 86 et al., 2006), the inconsideration of trade-offs between benefits (Seddon et al., 2020) and difficulties of 87 upscaling (Al Sayah et al., 2021) are major gaps to bridge. Overlooking the above-mentioned challenges 88 89 can lead to biased designs, conceptualization and implementation of NBaS. This in turn compounds the risks of maladaptation and multiplies the risks of disservices (Wickenberg et al., 2021). Other barriers such 90 91 as public acceptance, stakeholder participation, governance obstacles and funds (Al Sayah et al., 2021) are 92 also prevalent and can be considered as additional limiting factors.

93 While certainly win-win solutions, both NBS and NBaS are often portrayed as immune systems capable of 94 resolving the challenges they were introduced to face. In this sense, a great deal of importance is given to 95 the benefits derived from these solutions, particularly for human health and socioeconomic returns. 96 Although this representation might be favorable for increasing the public/political acceptance of these 97 solutions, it also widens the gap between the research community and practitioners by creating "language 98 barriers" as highlighted by the REGREEN project (Banzhaf et al., 2020). These barriers are mainly due to 99 the multitude of disciplines implicated in the design and implementation of these solutions. Therefore, for 910 properly unlocking the potential of these solutions, research are required to overcome the current paradigm 92 (Wickenberg et al., 2021), and develop further the science behind these solutions.

102 On the basis of what was presented, this study aims to compile an inventory of knowledge on NBaS with a 103 focus on European efforts through the H2020 program. To do so, the study first explores current advances on NBaS from relevant projects, extracts identified limits and ultimately proposes lines of work to develop. 104 The rationale behind this approach is that by providing a scientific meta-analysis, an overview of the EU's 105 progress is offered (Davies et al., 2021). Accordingly, the objectives of this paper are: (1) to study the 106 transition from NBS to NBaS in Europe (without narrowing the NBS concept to climate change adaptation 107 108 only); (2) unravel current and emerging research trends for NBaS; (3) providing a state-of-the-art on currently established NBaS knowledge and limits and (4) reviewing existing research gaps and proposing 109 lines of work to develop. At no point do the Authors undermine the importance of the societal, political and 110 111 governance domains of the concept. For fully unlocking knowledge on NBS-NBaS, the integration of these 112 angles is a must. However, this was beyond the scope of this review that solely focuses on the more biophysical angles of the concept. 113

114 **2.** Materials and methods

115 The workflow of this study consisted of a three-phased approach: search, filter, and extract/analyze. For the Search phase, the European Commission's Community Research and Development Information Service 116 (CORDIS) website [https://cordis.europa.eu/] was used to identify the relevant projects. The search query 117 118 consisted of "nature-based solutions" as a keyword. The "program" and "collections" filters were used to refine the search. Under the "program" filter, the H2020 box was selected, while the project box was 119 selected under "collection". The chosen date range was from 2014 onwards, as the latter marks the start of 120 121 the H2020 program. Within this interval, the year 2015 is one of the most important NBS landmarks in 122 Europe: the official integration of NBS into the EU's agenda (European Commission, 2015)

a) The first search (*search 1*) yielded NBS H2020 projects. The selected projects were then validated against
the Oppla database, and two EC-issued reports Wild et al. (2020) and Dumitru and Wendling (2021). The
first presents an analysis of EU-funded projects, while the second is the EC's most recent handbook for
evaluating the impact of NBS. As a first result, 41 projects were found. Given the scope of the study (i.e.
NBaS), a second refinement step was performed (*search 2*). The aim of search 2 was to zero in on strictly
NBaS related projects. For that purpose, each CORDIS webpage was revisited to determine under which
topic and program is the project listed. To this end, projects with the following topics were selected:

130 131	•	SC5-10-2016 - Multi-stakeholder dialogue platform to promote innovation with nature to address societal challenges.
132	•	SCC-02-2016-2017 - Demonstrating innovative nature-based solutions in cities.
133	•	SC5-09-2016 - Operationalizing insurance value of ecosystems.
134	•	SCC-03-2016 - New governance, business, financing models and economic impact assessment
135		tools for sustainable cities with nature-based solutions (urban re-naturing).
136	•	SC5-08-2017 - Large-scale demonstrators on nature-based solutions for hydro-meteorological
137		risk reduction.
138	•	SC5-13-2018-2019 - Strengthening international cooperation on sustainable urbanization: nature-
139		based solutions for restoration and rehabilitation of urban ecosystems.
140	•	LC-CLA-06-2019 - Inter-relations between climate change, biodiversity and ecosystem services.
141	•	SC5-14-2019 - Visionary and integrated solutions to improve well-being and health in cities.

- For further validation, the program heading in each project's CORDIS webpage was also examined forinclusion. Accordingly, the following programs were of interest:
- H2020-EU.3.5.1. Fighting and adapting to climate change.
- H2020-EU.3.5.1.2 Assess impacts, vulnerabilities and develop innovative cost-effective
- adaptation and risk prevention and management measures.
- H2020-EU.3.5.2.1. Further our understanding of biodiversity and the functioning of ecosystems,
 their interactions with social systems and their role in sustaining the economy and human well being.

To make sure that no project was left out, each project's website was then revisited. Accordingly, any elements related to the scope of the study in the project's impacts, description or objectives were considered as additional inclusion factors. Following *Search 2*, a total of 27 NBaS projects were retained. Each project's deliverables were then obtained from the CORDIS results tab as well as the project's webpage. This step was performed since some deliverables are not yet listed on CORDIS despite their existence on the projects' webpages.

- b) The filtering phase consisted of two steps. The first was a general approach where deliverables 156 were retained based on their titles, general content and relevant sections. At this stage it is important 157 158 to mention several elements: (1) textual material was compiled and collected during the January-159 July 2021 period. Therefore, any outcome following this period is not included. (2) At the time of this study several projects were still ongoing while others have only begun in 2020. Some were 160 affected by the COVID-19 pandemic while others were still in their pre-results phases. 161 162 Consequently, some projects had no deliverables during the study period. (3) Some projects had no/restricted access to deliverables and hence were unavailable. In order to account for these 163 shortcomings, the results packages on the related CORDIS webpage and scientific publications 164 (articles) issued from these projects were included where applicable. The inclusion of scientific 165 articles where applicable also contributed to the solidification and the enrichment of the study's 166 corpus as these are peer-reviewed by scientific experts. Projects from which scientific articles were 167 added are: ThinkNature, CLEVER Cities, Nature4Cities, PHUSICOS, REGREEN, RENATURE, 168 169 NATURVATION, Connecting Nature, CLEARING HOUSE, OPERANDUM, NAIAD, DRYVER, Urban GreenUP, PHUSICOS, and RECONECT. Accordingly, 21/27 projects with 137 deliverables 170 were passed to the second filtering phase. The second step was more specific and consisted of 171 172 examining the reports individually and entirely through careful reading of each.
- c) Finally, findings were extracted during the extract/analyze phase. At no point do the Authors assume that
 their findings are not debatable. The Authors acknowledge that some sample-related or selection flaws may
 be inherent. However, the best possible measures were taken to avoid any unjustified assumptions and to
 ensure a minimal error margin.

177 **3. Results and discussions**

This section provides a number of results and discussions grouped under different themes. Accordingly, the first section discusses the way NBaS are addressed in the H2020 projects. The second section discusses the NBaS terminology in H2020 projects and the NBS-NBaS transition, the third section discusses geographical distributions and gradients, while the forth section presents the target ecosystems and their challenges. The fifth section details current knowledge and limitations per ecosystem, while the sixth presents the same pattern per main research topics. Further details can be found under each throughout the different sub-sections.

185 **3.1. General presentation of the studied projects**

186 The retained projects are of different backgrounds and encompass several objectives for the use of NBS-

187 NBaS (Figure 1).

197 *RENATURE is not attributed to the same topics, but generally it can be listed under several ones.

198 Connecting Nature, GrowGreen, UNaLab and Urban GreenUP utilize NBS for climate and water resilience 199 in cities. Nature4Cities and NATURVATION investigate governance, business, finance and economic 200 models and assessment for NBS. The NAIAD project complements the actions mentioned-above by providing an assessment of the insurance value of ecosystem services. OPERANDUM develops NBS to 201 202 mitigate hydro-meteorological phenomena, URBiNAT focuses on regenerating and integrating deprived urban contexts through NBS, proGIreg harnesses the power of nature for urban regeneration, while 203 RECONECT aims to reconcile Europe with its citizens through democracy and the rule of law. PHUSICOS 204 205 will demonstrate how NBS can reduce risks in mountain landscapes in one the very few H2020 mountain

206 related projects. ThinkNature aims to develop a communication platform to connect various stakeholders 207 and to support the understanding and promotion of NBS at different geographical levels. RENATURE 208 builds a strategy and research cluster targeting NBS for sustainable development through scientific 209 excellence and innovation. EdiCitNet aims to explore the potential of Edible City Solutions in cities to increase social cohesion, equality, food security and adapt these solutions to the urban realm. CLEVER 210 Cities targets urban regeneration (social, environmental and economic improvements) through NBS. 211 212 CLEARING HOUSE aims to mobilize urban forest-based solutions for rehabilitating, restoring and 213 reconnecting urban settings. REGREEN aims to generate evidence on the integration of ecosystem services and biodiversity into NBS and to advocate the latter for urban planning. FutureMARES aims to provide 214 NBS for CCA and Climate Change Mitigation (CCM) in marine environments around Europe. EuPOLIS 215 aims to utilize natural systems (NBS) to enhance public health and well-being and create resilient urban 216 217 ecosystems. DRYvER aims to established strategies for the mitigation and adaptation to climate change 218 effects in dry river networks through the integration of hydrological and ecological (NBS) perspectives among other factors. 219

As can be noticed, the projects cover a range of different backgrounds, and possess objectives that do not

221 cover the same scopes. The different nature, scales, data, objectives and methods of the projects make

drawing parallel between them difficult. However, it is possible to draw on similar lines of work and

research needs.

3.2. On the NBS-NBaS terminology, concept and transitions

225 In terms of definitions, some projects adopt the EC's definition, others compare between the EC's and the IUCN's definitions (Cohen-Shacham et al., 2016), while many reformulate their own definition of the 226 227 concept. This discrepancy may reflect the various foci or interpretations. However, it can also indicate that the scientific progress behind the concept has not been fully transposed into the policy and management 228 229 angles (Grace et al., 2021). Two remarkable and important insights from H2020 projects stand out: 1) some 230 Authors believe that NBS are sometimes oversold (discussion in section 5.2.), and 2) others do not favor the term NBS in the first place. In this context, Bailly et al. (2019a) state the following: "NBS is a recent 231 232 European expression that is inappropriate. Experts and researcher prefer the term Nature. NBS can be 233 interesting to refer to the ecosystem services of nature, but tends to reduce nature to its utility without considering the others dimensions that surround it." 234

Throughout the projects, the transition from NBS to NBaS can be considered as progressively ongoing. This transition was noticed within the individual projects, but can also be attributed to a stronger emphasis on climate change adaptation within the NBS framework. It is safe to assume that this transition is a subject of study in Europe (since 2014 at least), and that several projects tend to extend their knowledge to extra-European contexts (namely in Asia and Latin South America). Clearly, the root causes of this ongoing transition and its future trajectory are interesting elements to study. However, such an analysis will require time to become fully possible.

242 **3.3.** Geographical distribution and analysis

The geographical distribution is presented in Figure 2. Several large scale projects such as full mountain
ranges, the EU scale or the EU's coastal environments are not represented in Figure 2 for display purposes
only. This is the case of the PONDERFUL, FutureMARES, MaCoBioS, Green CURIOCITY,
OPERANDUM, RECONECT, PHUSICOS and NAIAD sites. However, these were not excluded from the
analysis phase.

248

249 Figure 2: The geographical distribution of the retained projects' intervention sites, link to Google map:

 map 2: https://www.google.com/maps/d/u/1/edit?mid=11HBRW50gpm3RPbJ4L-0025KS00yIbru2&usp=sharing color code:

251 map 2. <u>https://www.google.com/maps/arti/real-imag-fillbkwjoggmiski/oi-p-0025k500yth/u2cusp-sharing</u> color code.
 252 grey refers to urban pilot sites, blue to freshwater/watersheds and green for natural areas. A detailed representation of each
 253 projects NBS-NBaS can be found on <u>https://cloud.enpc.fr/s/damrKF3zZzpCKiT</u>

254 As can be seen from Figure 2, many sites are scattered across the European continent. Accordingly, the 255 most targeted climatic regions are the temperate continental climate, the oceanic and northern temperate regimes and the Mediterranean climate (Nikolaidis et al., 2019). The interest in the latter is particularly 256 257 translated by the dense concentration of pilot areas in Southern Europe. This can be attributed to the 258 following reasons: 1) The Mediterranean climate is expected to be the most impacted by climate change 259 and its manifestations (Finér et al., 2019; Grace et al., 2021); and 2) The need for more evidence on the efficiency and co-benefits of NBS-NBaS as well as on the ecological responses of Mediterranean 260 ecosystems under changing environmental conditions (Balzan et al., 2020 and IUCN 2019 in Grace et al. 261 2021). Northern and Eastern Europe display scattered concentrations with much less sites in the Eastern 262 part. This may be due to: 1) the limited number of scientific publications on NBS in Eastern Europe since 263 2005 (Cooper et al., 2018), 2) the lesser number of scientific publications on NBS-NBaS in Eastern Europe 264 265 with respect to the Western counterpart (Hanson et al., 2017) and 3) less projects are based in this region. At a finer scale, Figure 3 shows that most pilot sites are concentrated in Italy, Spain, Germany and France. 266

273 Figure 3: Location of the pilot sites of European countries in H2020 projects

274 3.4. Target ecosystems, challenges and NBaS

275 The targeted ecosystems in each project are presented in Figure 4 (from each project's pilot sites). As can be seen, the urban environment predominates the H2020 NBaS projects landscape (61%). This distribution 276 reflects the current European strategies that are mostly focused on cities and urban contexts under climate 277 278 change and demographic development. However, this interest comes at the expense of other media that are 279 significantly underrepresented and understudied. Accordingly, the coastal (9%) and mountainous 280 environment (3%) are remarkably overlooked with coastal resilience and marine protection being one of the least targeted goals (Hanson et al., 2017; Nikolaidis et al., 2019; Ruangpan et al., 2020; Veerkamp et 281 al., 2018), while mountainous environment is only targeted by a single project (PHUSICOS). Strikingly, 282 the agricultural medium is absent as a distinct ecosystem, despite its marginal occurrence as pilot 283 284 intervention site in some projects.

285

286 Figure 4: Target ecosystems of H2020 NBaS projects

In terms of climatic challenges, urban heat islands, coastal hazards (mostly in relation to urban coastal settings), floods, sea level rise, heavy rainfall, temperature rises, heat stress, erosion, landslides, and storm surges are the most addressed. From these challenges, flooding occupies the top position and is almost present in all intervention sites (Debele et al., 2019). Urban Heat Islands (UHI) are the second topmost

9

addressed challenge. While UHI mostly concern the urban environment, other challenges are crosssectorial. However, the focus on urban ecosystems, as a result of the increasing number of urban populations, reduces the efforts needed to address the above-mentioned challenges in other media. Another tier of challenges throughout the projects focus on socioeconomic disadvantages, social inequities, vulnerable populations' status, human health, environmental and resource degradation, overpopulation, air quality, reduction of green cover, agricultural decline, etc. However, these are beyond the scope of this study as the latter focuses more on the biophysical angles of NBS-NBaS.

298 The dominant focus on urban ecosystems makes urban green solutions (green parks, urban forests, 299 ecological corridors, etc.) and blue-green infrastructure (green roofs, urban wetlands, ponds, grass waterways, etc.) the most studied type of NBaS, thus missing out on a variety of other non-urban solutions. 300 Moreover, targeting the urban realm which ranges from the building to the city level at best, relatively 301 302 covers small scale interventions. This "narrow scale" approach leads to missing out on macroscale interventions and subsequent large scale NBS-NBaS. Given the large focus on urban systems, most 303 304 presented solutions correspond to Type 3 (i.e. NBS that target the management or creation of new ecosystems, e.g. urban parks, green roofs, etc.), and to a lesser extent to Type 2 NBS (i.e. interventions in 305 managed ecosystems and landscapes, e.g. agrobiodiversity, agroecology, etc.). Type 1 (i.e. minimal 306 307 interventions - protected ecosystems, e.g. protected areas) are relatively rarely to never targeted. This 308 distribution signifies that most efforts are concentrated on a particular type of NBS-NBaS, leaving behind and potentially missing out on the potential of others. These observations converge with those of Wendling 309 et al. (2019) who reported that most European NBS are of type 3 nature. 310

311 **3.5.** Current knowledge and limitations per ecosystem

312 In this section, a state-of-the-art from H2020 literature on current knowledge and identified limits is 313 presented. Outcomes of this section were the basis for formulating the research perspectives and lines of 314 work proposed in the conclusion section.

315 *3.5.1. The urban ecosystem*

316 The European Commission focuses mostly on the urban medium due to two main reasons: i) the increasing 317 number of European populations living in cities, and ii) the urge to address numerous challenges, namely climate change, impacts on human health, and the degradation of natural capital (Cohen-Shacham et al., 318 319 2019). Despite being major contributors to climate change, and one of the most affected contexts, cities can also be part of the solution (Arlati et al., 2021; Gerstetter et al., 2020; Knoblauch et al., 2019; Tozer and 320 Xie, 2020). This is mainly due to the long term accumulation of emitted carbon dioxide in urban vegetation 321 322 and underlying soils as underlined by Richter et al. (2020) for the CLEARING HOUSE and Connecting Nature projects. 323

324 The concept of NBS is the most recent entry in the debate on nature's role for increasing the climatic resilience of urban settings (Bailly et al., 2019b; O'Sullivan et al., 2020). In urban settings, NBS are being 325 developed as part of urban climate infrastructure strategies for which cities use resilience principles as a 326 guiding framework (Oke et al., 2021). According to the CLEVER Cities framework, the logic behind this 327 approach is that NBS allow progress towards flexible and equitable urban resilience while promoting CCA 328 329 (Mahmoud and Morello, 2018). According to the euPOLIS project, NBS are also considered as key factors for retrofitting and rehabilitating existing urban areas (Maksimovic et al., 2021) and also contribute to urban 330 biodiversity (Xie and Bulkeley, 2020). For the REGREEN project, at this level the role of biodiversity is 331 multi-leveled: a) it can be part of the NBS-NBaS, b) it can serve as an important attribute to help the sought 332 solutions withstand pressures such as climate change, or c) it can be obtained as an end product from the 333 implemented solution (Fletcher et al., 2020). Nonetheless, as highlighted by the NATURVATION project, 334 the approach to urban NBS-NBaS biodiversity is not very centric, but rather focuses on ecosystem-based 335 approaches for protecting and restoring functionalities, or ensuring the connectivity of habitats (Xie and 336

337 Bulkeley, 2020).

338 Most research on NBS in the urban environment is biased towards disciplinary perspectives (Haase et al., 339 2014 in Veerkamp et al. 2018). In this regard, according to the Connecting Nature project, there is a new 340 role of science with cities instead of science for cities (Holscher et al., 2019). Science for cities represents 341 a somehow rigid approach where generated knowledge is often trapped in disciplinary silos. On the other hand, science for with cities is perhaps a more flexible concept as it includes the active participation of the 342 city's inhabitants and other urban stakeholders. Accordingly, the shift from "science for" to "science with", 343 344 ensures the democratization of knowledge on cities (Carton and Ache, 2017 in Holscher et al. 2019). 345 However, as most city science is generated by consultants, scientific researchers are needed to generate 346 new knowledge in addition to synthesizing already existing information (Holscher et al., 2019). To this end, a scientist's critical logic can be beneficial for providing perspectives and recommendations that take into 347 consideration the complexity of cities and the urban climate (Steiner, 2014 in Holscher et al. 2019). 348 349 However, many elements related to the urban realm still pose significant challenges for this task, these can 350 be considered as current knowledge limits that should evolve into research lines of work:

351 First, the relationship between nature and cities is inversely proportional for its most part (Bailly et al., 2019a). In this regard, there is a need to clearly define all aspects of the city-nature relationship and 352 determine how the trade-offs between these two different ecosystems (urban-nature) can be balanced in 353 354 terms of service provision and delivery, as well as to understand the negative feedback loops and counteract 355 them. Second, the urban context is highly non-uniform as it is formed from a mosaic of different systems, landscapes and media (Bulkeley and Raven, 2018). Similarly, urban nature extends beyond the 356 misconception of scarce vegetation and artificial nature, and englobes water, lands, soils, air, and energy 357 (Bailly et al., 2019b). The often oversimplified representation of the urban realm undermines the 358 contribution of different land cover elements to the modification or creation of services or processes (Babí 359 360 Almenar et al., 2018). Therefore, according to Nature4Cities, any approach should consider this 361 heterogeneity to adequately define the challenge in hand and the subsequent solutions. Nonetheless, 362 complex approaches to mosaics of ecosystems are still rare. This is due to the fact that ecosystems, much like their services, are not bound by geographical boundaries, which means that these engage in loops that 363 aren't still well understood. To this end, a mosaic of ecosystems means different tipping points, different 364 365 ecological thresholds and different responses. Therefore, no solution can be accurately designed without a sufficient understanding of the stated elements. While this aspect is certainly difficult and bound by many 366 367 challenges, it remains a necessary line of work to develop.

368 Third, ongoing urbanization constrains planners and scientists to design solutions in continuously limited spaces (Knaus and Haase, 2020). This is also compounded by the fact that turning impervious areas to green 369 or blue spaces often conflicts with the need of building more housing structures. Therefore, space-sensitive 370 solutions are needed (Knaus and Haase, 2020). Nonetheless, space-sensitive solutions often imply small-371 scale interventions. The efficiency of small-scale interventions, particularly for large scale challenges such 372 as climate change is yet to be decisive. To this end, NBaS for microclimate adaptation (i.e. a proportional 373 374 scale to the proposed solutions) might be a more logical approach to develop. Fourth, the urban setting is a 375 multi-scalar context, it encompasses different scales from the building, to the urban zone and ultimately the cityscape level (Somarakis et al., 2019). The multiplicity of scales complicates the choice of a scale-efficient 376 377 solution. For instance, a green roof at the building scale will have a negligible effect at the cityscape level 378 in terms of cooling. Likewise, an urban park at street level while have negligible effects at the building 379 scale.

Lastly, isolated NBS-NBaS (small interventions) can collapse under the "harshness" of the urban realm where entwined pressures may significantly surpass the solutions' capacity and cause an inflexion of their functions (Bailly et al. 2019a). In this vein, understanding the interactions between the solution and the medium it has been introduced in is an important platform to consider. Often, NBaS are wrongfully introduced as immune systems without considering how the components of the ecosystems they were introduced into influence their survival/efficiency. The most studied solutions are urban parks and forests, followed by urban green spaces, blue areas, and community gardens (Cooper et al., 2018). Accordingly, there is a need for mapping and deriving more evidence from a wide range of NBS other than Blue GreenInfrastructure (BGI) (Hanson et al., 2017).

389 *The urban climate, water management and related solutions*

390 What differentiates the urban medium from others is its particular climatic behavior. This is mainly due to the multitude of land covers that form the urban settings and the morphology of cities (degree of 391 392 compaction, building heights, extension and sprawling). UHIs are the most studied and documented urban 393 climate phenomena (Bailly et al., 2019a). According to the GrowGreen project, they have become central elements of planning particularly under an ever changing climate (Gutierrez et al., 2020). Water 394 management comes second after UHI and is particularly addressed for stormwater management and urban 395 flooding reduction. In response to both challenges, green cover expansion and green roof installation are 396 the most frequent solutions throughout the retained projects. In what follows, an explanation of each one's 397 effects along with knowledge needs are presented 398

399 Trees

400 Street trees, along with other types of plantation, are considered as some of the most used solutions for 401 attending to UHIs. Through evaporative cooling they tend to reduce local temperatures while enhancing air 402 quality through photosynthesis. Nonetheless, there have been reports on disruption of air flows and creation 403 of localized heat pockets as a result of tree configurations. In addition, negative effects on air quality have 404 been reported due to blocking of ventilation within street canyons as a result of specific configurations of 405 connected trees.

406 Trees are also considered as key elements for stormwater management in urban settings through 407 precipitation interception, runoff reduction, increased evapotranspiration and infiltration (Baker et al., 408 2021). However, as highlighted by Baker et al. (2021) in the REGREEN project, the extent of their 409 efficiency has yet to be defined, and related literature hasn't been objectively reviewed. They are also efficient measures for reducing temperatures through evaporative fluxes and shading. According to the 410 Connecting Nature projects, if tree-based solutions are imperfectly designed, they can disrupt air flow, 411 hence causing localized increases in air temperatures (Connop et al., 2020). While the general consensus is 412 that temperature increases in urban environments will only worsen UHIs, these may also induce longer 413 vegetation growing season, increased photosynthesis rates, and hence more carbon storage (Vasenev and 414 415 Kuzyakov, 2018 in Richter et al., 2020). This could also possibly mean promoted cooling as a result of biomass growth or development. Nonetheless, these feedbacks should be better understood when an NBS-416 NBaS is designed. At this level, according to proGIreg, the definition of buffer zones for the analysis of 417 418 NBS-NBaS impacts could be helpful as their effect may not extend beyond a certain zone (Leopa and Elisei, 419 2020) particularly for cooling. The arrangement of trees in cities dictates the nature of the solution, however 420 evidence on the effect of tree arrangement for maximizing performances and benefits is inconclusive (Baker et al., 2021). Considering this aspect is important as tree arrangement is often dictated by space availability 421 422 in cities. Regardless of their sizes and arrangements, trees and green covers address CCA and Climate 423 Change Mitigation (CCM) simultaneously as they can sequester carbon while reducing temperatures (Tozer and Xie 2020). However, prior to the design and implementation of any green solution, several factors 424 should be accounted for. For instance, some green solutions are irrigation dependent. This raises concerns 425 in terms of resource efficiency, particularly in the context of climate change where water scarcity is 426 expected to increase and droughts to extend further. In this context, the resource efficiency (consumption 427 428 versus generation/conservation potential) of any planned solution should be better investigated as 429 throughout their existence NBaS consume natural capital in their own rights. Understanding how NBS-NBaS utilize natural resource and nature is relatively an unexplored line of work. 430

Even if green spaces are perceived as performant NBS-NBaS, heatwaves and extended drought periods
can severely degrade them (Morakinyo et al., 2017). Additionally, tree (particularly juvenile ones) survival
rate is very low during the first year as these are prone to be affected by climate change and particularly

heat stress (Richter et al., 2020). Accordingly, what seems to be a solution to an intended problem can alsobe susceptible to the challenge it was intended to address.

436 *Green roofs: A solution for limited spaces*

437 Green roofs are very widely targeted under various H2020 urban projects. As reported by Urban GreenUP, in cities infrastructural and space availability challenges can limit the expansion of NBS-NBaS (Kuban et 438 al., 2019). That is why cities often cannot support large NBS projects (Bailly et al., 2019b). For this purpose, 439 440 green roofs are considered as some of the most effective multi-purpose "ground-free" solutions that are ideal for cities and their continuous densification (Knaus and Haase, 2020). According to Zölch et al. (2017) 441 442 in Baker et al. (2021), green roofs even outperform trees in terms of runoff reduction due to their larger permeable surfaces when aggregated, as opposed to the limited surface of trees planted in urban settings. 443 The most decisive factor for a green roof is its substrate as it also defines its type, i.e. extensive or intensive 444 445 (Knaus and Haase, 2020). Most green roof studies focus on extensive roofs rather than intensive ones 446 (Knaus and Haase, 2020), despite the fact that the latter outperform the former on an environmental scale 447 (Morakinyo et al., 2017 in Knaus and Haase, 2020). In this vein, intensive green roofs are more efficient in terms of stormwater management, control of dissolved pollutants, evaporative cooling as a result of higher 448 biomass indices, and biodiversity support (Cascone, 2019). 449

450 Regardless of their types, these roofs are mainly used for climate resilience and long-term urban water 451 management (Snep et al., 2020). They are important surfaces for ecological compensation in cities, and 452 have a large potential for renaturing urban contexts (Santos et al., 2016). They effectively retain incoming 453 water, help in CCA/CCM, modify surface energy balances, reduce runoff/peak flows, and promote urban 454 biodiversity (Pardela et al., 2020). Whether intensive or extensive, the performance of green roofs for 455 stormwater management is highly related to rainfall events and the initial saturation of their substrate.

Many studies report several insights on the behavior of green roofs on peak reduction and water retention
However, lesser studies focus on assessing their impact on temperature reduction (Jamei et al., 2021). In a
study on the effect of green roofs' in a neighborhood located in central Berlin Germany, Knaus and Haase
(2020), found the following:

460 i) In relation to the CLEARING HOUSE and CONNECTING Nature projects, at a street level, the cooling effect of green roofs is very minor with values as low as 0.04°C (mean temperature reduction). On a 461 462 pedestrian level, the maximal reduction effect is of 0.3 °C (with a mean of 0.1 °C), also negligible. ii) The most pronounced effects on temperature are observed at the roof's level with a decrease of surface 463 temperature by as much as 26 °C, Physiological Equivalent Temperature (PET) by 4 °C compared to street-464 level, and by 9 °C when compared with a non-green roof, and iii) in areas of mid to high buildings, the 465 down spill of cool air generated by green roofs hardly reaches the street. According to Müller et al., (2014) 466 467 in Knaus and Haase (2020), the downward effect of green roofs is negligible for buildings higher than 10 468 meters.

469 However, these findings are case-specific and are applicable to the specific conditions they were found in (Davis et al., 2018). In a different climatic setting, different behavior could be expected. Regardless of their 470 exact number, in general terms the above-mentioned findings indicate that the effect of green roofs is only 471 472 pronounced at the level of the building they are located on, and hence do not replace ground greening (in terms of cooling), but can be only considered as a complementary effort (Knaus and Haase 2020). However, 473 when considering the surface of green roofs when spread over the city, a considerable increase of green 474 cover can be noted (Knaus and Haase 2020). Another advantage of green roofs is that these can be coupled 475 to other solutions. For instance, urban farming on a green roof (Somarakis et al., 2019), or a constructed 476 wet roof that combines an extensive green roof and a constructed wetland for water treatment (UNaLab, 477 2019). However, further investigations on the combined effects of ground and roof solutions are still a line 478 479 of work to develop.

480 *3.5.2. Freshwater ecosystems*

481 The freshwater medium is the second most targeted ecosystem under the H2020 projects. In each project, different freshwater realms of various scales are present. These range from lakes, to rivers, to river networks 482 and watersheds. Most of the prevalent measures are of structural or functional measures. Examples are river 483 484 restoration, floodplain enlarging, river meandering, daylighting, installation of levees, wetland restoration, modification of the hydrologic network (connection/disconnection), retention basins and others. At this 485 486 level, nature contributes to CCA through flood management and the provision of better water quality (Bailly 487 et al., 2019b). Water quality is mainly addressed through phytoremediation, the use of wetlands or other 488 small water retention features for sediment or soil bound pollutant retention. Another measure is the installation of grass or vegetation belts and canals around waterbodies to protect the latter from pollutant 489 bound runoff from neighboring systems (urban or agricultural). In river management and flooding, several 490 491 projects highlighted many factors that are responsible for the complexity and difficulty of NBS-NBaS. 492 According to the ThinkNature project, the multitude of factors that interfere [i.e. socioeconomic, climatic, 493 geological, and geomorphological, etc] (Banwart et al., 2018) make the design and conceptualization of these solutions complicated. Moreover, the challenges involved call for different scales, and that itself is a 494 considerable barrier; for instance, pluvial flooding requires an urban zone scale, while river flooding 495 496 requires a whole watershed scale approach (Somarakis et al., 2019). For NAIAD, the role of ecosystems 497 (underlying basis of NBS and NBaS) on water supplies is still an open empirical research topic (Hérivaux et al., 2019). Also, the size and location of NBS-NBaS is also an important factor to consider. According 498 to Burke et al. (2018) as part of the NAIAD project, small (many) interventions should be concentrated in 499 upper watershed sections where flows are less than the downstream parts where large interventions should 500 501 take place.

502 For OPERANDUM, the same hazard, e.g. flooding, can be initiated by different triggering factors. For instance, river floods can be initiated by precipitation in a particular context (e.g. Western Europe), while 503 in other regions (e.g. Northern Europe), snow melt can be the main reason (Aguzzi et al., 2019). An example 504 505 would be the case of Finland (Finér et al., 2019), where significant efforts are needed to take into consideration the effect of melting, its timing (changes) and the effects on the sought solutions. 506 Accordingly, sought solutions in these contexts should take account for these manifestations along with 507 other ones. Therefore the same NBS-NBaS for the same freshwater hazard cannot be applicable in different 508 509 locations.

510 In terms of flooding, NBS-NBaS are designed to increase floodwater storage capacities upstream of the studied contexts (Muligan et al., 2017). Storage capacities usually concern four compartments: water 511 bodies, canopy, floodplains and soil (Muligan et al., 2017). Increasing the storage capacity of any 512 compartment impacts flood hydrographs by reducing the velocity of floodwaters, influencing peak flows 513 514 and buffering risks in both the river and downstream sections (Muligan et al., 2017). Van Soesbergen and Mulligan (2018) found through storage capacity analyses that targeting soil and canopy storages was needed 515 to reduce flood risk. While several NBS-NBaS target the floodplain (e.g. floodplain enlarging), water body 516 (e.g. river restoration and daylighting) and canopy compartments (e.g. increase of green cover), rare are 517 those who target soils despite the fact that increased soil infiltration can significantly reduce flood risks 518 519 (Muligan et al., 2017). Infiltration solutions are also potent drought NBS-NBaS as these can increase groundwater storage (Muligan et al., 2017). However, groundwater systems are not routinely monitored 520 (Douglas et al., 2019). Moreover, increased infiltration is not always an advantage as in contexts where 521 522 groundwater supply is high increasing infiltration will only compound groundwater flooding risks due to water table rise (Hérivaux et al., 2019). A relevant example is karst saturation as the latter can lead to 523 524 amplified risks particularly when soil saturation is also high (Graveline et al., 2018). It is also important to 525 understand how NBS-NBaS can influence groundwater levels after extreme events (Pérez-Lapena et al., 526 2018). In this vein, the groundwater-aquifer-NBS nexus has been highlighted in several sources (such as 527 the OPERANDUM project) as a significant gap to address particularly given their importance for attending to droughts and floods simultaneously (Tuomenvirta et al., 2019). 528

529 Currently, flooding is mainly addressed using hybrid solutions (Debele et al., 2019). According to CLEVER 530 Cities, in the green versus grey debate, NBS-NBaS often lose the argument of collected experience and 531 evidence compared to grey infrastructures (Knoblauch et al., 2019). Therefore, the ThinkNature project underlines the need to develop tools and indicators for assessing mixed solutions (Nikolaidis et al., 2019). 532 According to NATURVATION, the environmental impact of hybrid solutions also requires further 533 investigations (Kiss et al., 2019). It is therefore logical to question if NBS-NBaS are fully capable of 534 535 masking the disruptive effect of their grey counterparts. For RECONECT, the latter's performance under 536 an uncertain evolution of climate is also still relatively unknown, and can be considered as an important line of work to explore (Watkin et al., 2019). Under this context, significant efforts are needed for the 537 assessment of large scale NBS-NBaS, watershed scale NBS-NBaS and hybrid structures that contain both 538 539 small and large NBS (Watkin et al., 2019).

540 It is worthwhile mentioning that an important aspect of freshwater systems is targeted through the DRYvER project. The latter is the only H2020 project that considers intermittency of water bodies. Although the 541 542 project is still undergoing, the work done by Messager et al. (2021) provides solid arguments on the gaps 543 this project is filling. According to the same Authors, unlike rivers and permanent streams, the value and future of intermittent water bodies are often undermined, understudied and overlooked (Messager et al., 544 545 2021). Until recently, freshwater sciences were particularly concentrated on perennial water bodies, and it 546 isn't until lately that scientists acknowledged the seriousness of intermittent water bodies' degradation (Messager et al., 2021). As a result, the related scientific methods and management tools are either limited 547 548 or absent (Messager et al., 2021). In a map presented by the same Authors, stream intermittency was shown to be particularly pronounced in Southern Europe (i.e. the region under Mediterranean climate) where 549 droughts are causing significant stress on water resources. However, as mentioned-above, this discipline is 550 551 still nascent and more significant efforts are needed.

552 3.5.3. Marine and coastal ecosystems

553 The EC's seven NBS actions for R&I are according to Morello et al. (2018): Urban regeneration through NBS, NBS for well-being in urban areas, NBS for coastal resilience, multi-functional nature-based 554 555 watershed management and ecosystem restoration, NBS for sustainability of the use of matter and energy, 556 NBS for enhancing the insurance value of ecosystems, and NBS for carbon sequestration. Despite the high rank of coastal resilience on this list, coastal areas are very rarely addressed within the NBS-NBaS 557 framework (Ruangpan et al., 2020) and through the H2020 NBaS projects. In a review performed by 558 559 Hanson et al. (2017), climate action for adaptation, resilience and mitigation were found to be NBS priority number one, while coastal resilience was quasi-absent. Another review by Nikolaidis et al. (2019) for case 560 561 studies in the ThinkNature database revealed that coastal resilience is also one of the least targeted goals. The same was also found in a review conducted by Veerkamp et al. (2018), where climate adaptation, 562 563 resilience and mitigation were found to be the most targeted aspects within ecosystem service assessment, in contrast to coastal resilience and marine protection. Several of the retained projects target coastal areas 564 as part of their pilot zones. However, only two H2020 NBaS project are dedicated for coastal and marine 565 areas (FutureMARES and MaCoBioS). Both are still undergoing (2020-2024) and consequently not many 566 related references have been produced during the time of this study. Therefore, not much research gaps 567 were extracted from these projects. 568

However, a general picture of current knowledge shows that the underrepresentation of marine and coastal 569 ecosystems is surprising, since these are some of the most influenced contexts by hydrometeorological 570 571 hazards and climate change (Debele et al., 2019). The complexity of these settings might be a reason (Dudley et al., 2010), as challenges in these systems may be closely overlapping [e.g. coastal resilience and 572 climate change] (Bulkeley and Raven, 2018). Some hazards may be also interlinked, for instance storm 573 surges and coastal erosion have a cause-consequence relationship (Debele et al., 2019). Under the current 574 575 reviewed offer (excluding FutureMARES and MaCoBios), coastal erosion is an addressed hazard in coastal 576 urban contexts (coastal cities). The main objective behind this approach is to protect or adapt the concerned

577 cities to coastal hazards. As such, coastal resilience and the coastal ecosystem are not targeted for land loss, 578 sediment balance, foreshore stability or seafloor configuration (i.e. the ecosystem's intrinsic value), but for 579 the sake of the urban system. This indicates that the importance of an ecosystem increases only when an 580 urban context is in vicinity. Subsequently, the proposed NBS-NBaS will be indirectly implemented as utilitarian anthropocentric interventions. Moreover, the solutions offered by marine and coastal ecosystems 581 are also somewhat underutilized despite their potential. For instance, marine habitats such as seagrass, salt 582 marshes, mangroves, coastal wetlands and kelp forests, coral and shellfish reefs are efficient coastal 583 584 protection elements that help adapt to increased storms, sea level rise and climate change induced floods 585 (FutureMARES, 2021). For example, salt marshes and coral reefs are capable of decreasing flood waves by 70% and 72% on average (Debele et al., 2019). However, these are still underused and are not studied 586 as much as green or blue-green solutions. Much of these solutions are expected to be implemented and 587 588 studied in the FutureMARES and MaCoBioS project, and hence considerable knowledge is expected to be 589 generated. However, during the time of this study, no data was yet available.

590 3.5.4. Mountainous ecosystems

591 The mountainous medium is the least targeted ecosystem in H2020 projects. The only dedicated project is PHUSICOS that aims to demonstrate how NBS can reduce risks in mountainous landscapes. Currently, 592 none of the present platforms on NBS are specifically focused on natural risks in hilly and mountainous 593 regions (Baills et al., 2021), nor on climate change adaptation. Despite the role of mountains in amplifying 594 595 hydrometeorological risks, particularly under a changing climate, not much attention is given to these 596 environments especially in European Disaster Risk Reduction (DRR) plans (Autuori et al., 2019). 597 Accordingly, very little research on NBS for DRR in mountainous environments has been conducted so far 598 (Accastello et al., 2019 in Martin et al., 2019). In the very few studies, most address floods while fewer 599 target landslide and rockfall hazards (Baills et al., 2021). To this end, success stories of NBS-NBaS for landslide and flood mitigation in rural and mountainous areas are still meagre (Solheim et al., 2021). When 600 considered, most solutions consist of forests (afforestation/reforestation) for stabilizing slopes, reducing 601 rockfall, landslides and avalanches as well as for buffering flood risks. 602

603 3.5.5. Forest and natural (protected areas) ecosystems

Within most of the retained projects, forests are some of the most common solutions (e.g. Clearing House, 604 605 OPERANDUM, euPOLIS, RECONECT and UNaLab, etc.), but are rarely addressed as target ecosystems. 606 The range of environmental challenges that forests are used as solutions to is wide, and spans across climate change adaptation/mitigation, disaster risk reduction, biodiversity support, climatic regulation, stormwater 607 608 management, air regulation, erosion counteraction, water quality support, floodplain restoration, and others. Seemingly, trees and forests are "the" solution for almost all environmental challenges in different 609 ecosystems. Under the retained projects, most of their use was concentrated in the urban ecosystem. Within 610 the latter, urban forests are designed/implemented for various objectives. For instance, in the URBiNAT 611 project, urban forests in Brussels (Belgium) are proposed as solutions for urban heat island and flood 612 613 mitigation. Under Nature4Cities, urban forests are used among other solutions for rehabilitating the 614 waterfront of the Tisza River in the Szeged Municipality of Hungary. In the same project, urban forests are used in Alcalà de Henares (Spain) for heat comfort, as part of edible solutions and for renaturalisation. For 615 616 the Clearing House project, urban forests are used in Barcelona (Spain) for river catchment restoration and for the delivery of green infrastructure strategies. In Brussels (Belgium), urban forests are used for 617 enhancing urban-rural territorial linkage, while in Gelsenkirchen (Germany), they are used as means for 618 619 restoring former mining sites, urban and sociocultural regeneration. In Kraków (Poland), urban forests are used for air quality improvement, while in Leipzing-Halle (Germany) they are used for river catchment 620 restoration, increasing the attractiveness of the site and for nature connectivity. 621

In other than urban systems (namely the mountainous environment and watersheds), forests were mostlyused for risk reduction (landslide and flood risk reduction, respectively).

624 In their own right, protected areas are relatively untapped despite their spread across the European continent 625 (Natura 2000, regional parks, and others). This is a major research gap to address, as the potential of these 626 solutions is relatively underutilized in NBaS projects. This could be due to the fact that the urban medium 627 is the most favored ecosystem, and that protected areas do not correspond much to urban priorities. However, when implemented at the outskirt of cities or urban contexts, protected areas can increase the 628 connectivity between urban, peri-urban and rural contexts, thus promoting the resilience of urban 629 630 ecosystems (Naumann and Davis, 2020). Moreover, the use of protected areas as means to protect other 631 NBaS is not very developed. While some projects propose the use of buffer strips to protect downstream 632 waterbodies from agricultural runoff, none make use of protected areas for the same purpose (protection of other NBaS). This could be an interesting line of work to develop for maximizing the use of protected areas 633 as part of NBaS or for their protection. In terms of marine protected areas, the narrow focus on marine 634 635 environments can also be a reason for the relative absence of protected areas. On these bases, significant 636 efforts are needed to leverage the use of protected areas (both terrestrial and aquatic) as NBS-NBaS, and to define relevant knowledge and research needs. The latter might be addressed throughout the EU's far-637 reaching 2030 biodiversity strategy that will transform at least 30 percent of Europe's lands and seas into 638 effectively managed protected areas (GEF, 2020). 639

640 *3.5.6. Agricultural medium*

The agricultural medium as an ecosystem of interest is absent. Many projects target agriculture in some related pilot sites, however not as a primary focus. The absence of the agricultural sector as a biome of interest is a significant element to consider given the importance of the latter for food security and the sustainability of humans and ecosystems. While edible solutions have been proposed as part of urban agriculture in the EdiCitNet project, very few other solutions are proposed. The reduced interest in the agricultural sector causes a subsequent underrepresentation of agricultural NBS-NBaS, and hence underlines a major gap to address.

648 **3.6.** Current knowledge and limitations per main research topic

649 *3.6.1. Climate change and adaptation*

650 A wide range of discussion on the underlying concepts and bases of climate change is available throughout the different references. The current red line threshold is the 2 °C increase, beyond which climate change 651 652 is assumed to become dangerous and its effects on ecosystems irreversible (Garcia Blanco et al., 2021). Therefore, adaptation to climate change stands first among the priority areas mentioned in international. 653 European, national, local and regional policies reviewed by Knoblauch et al. (2019). Mitigation of climate 654 655 change is also of equal importance, in an effort to keep warming beyond the 2 °C limit. All projects agree with Grow Green's insight that in the face of a changing climate, adaptive policymaking is needed to 656 657 account for uncertainties, while a certain degree of flexibility is inevitable to avoid robust decision making 658 (Zorita et al., 2021). The importance of research at this level lies not only in the generation of a successful solution, but also in refining interventions once implemented (Naylor et al. 2012 in Kiss et al. 2019). A 659 660 general agreement on the importance of environmental risk evaluation for ensuring the success of NBaS and NBS for CCM (Garcia Blanco et al., 2021) is also common between the projects. Most projects 661 approach CCA from the IPCC's (2014) perspective, where risk is expressed as a function of hazard, 662 exposure and vulnerability. To this end, an analysis of all three risk components is often seen throughout 663 the projects. Accordingly, this can be considered as a lever to overcome the classical confusion between 664 665 risk and hazard in climate-related risk assessments (Kumar et al., 2019). Nonetheless, several challenges 666 are apparent due to the difficulty of calculating/quantifying the occurrence probabilities for climatic hazards (Kumar et al., 2019), and the short-term variability of exposures and vulnerabilities due to intra annual 667 668 variations (Fletcher et al., 2020).

In the case of NBS (including NBaS), mitigation and adaptation are closely entwined as any adaptation
 activity will promote mitigation potential and subsequently promote climate resilience (GMV et al., 2019).

671 To this end, both NBaS and NBS for CCM commonly aim to enhance ecosystemic resilience and stabilize ecoservices (Morello et al., 2018). For NBaS specifically, the aim is 1) to preserve the services needed by 672 673 humans to make the impacts of climate change less adverse (Bailly et al., 2019b); and 2) to decrease the impact of the expected climatic effects (Morello et al., 2018). However, it is possible for a NBaS to target 674 CCM (Morello et al., 2018), hence the advantage of these solutions. For example, a green park established 675 from reducing the Urban Heat Island (UHI) effect [CCA] can simultaneously store carbon in its above and 676 677 below ground components [CCM]. Another strong point of NBaS is that they cover the cross-cutting elements of climate action, i.e. environmental, social, cultural, and economic factors (Tozer and Xie, 2020) 678 679 through the provision of multi-benefits. Xie and Bulkeley (2020) reported that NBaS and NBS for CCM were found to operate on five levels: 1) flood prevention and regulation, 2) UHI mitigation, 3) carbon 680 sequestration-reduction of emissions, 4) microclimate enhancement and 5) drought and desertification 681 682 prevention or reduction. From the levels mentioned, one can notice that some elements are related to climate change impacts mitigation rather than CCM itself. In the same vein, levels 1 and 5 are closer to adaptation. 683 This intersection between CCA and CCM underlines the mutually beneficial nature of NBS-NBaS, hence 684 their importance for action on climate. 685

In the case of NBaS, current research efforts are mostly focused on green infrastructures, ecological connective functions and ecoservices provision for climate change resilience (Collier, 2021). However, a significant knowledge gap for assessing the impact of NBaS across a range of climate resilience challenges, and through different geographic levels exists (Somarakis et al., 2019). Another gap concerning the assessment of their long-term effectiveness under climate change scenarios is also prevalent (Bowyer et al., 2020; Gómez Martín et al., 2021). This last point should be particularly focused on as it can help understand the conditions these solutions will face and will have to perform under (Bowyer et al., 2020).

693 From the five levels listed by Xie and Bulkeley (2020), flood (Debele et al., 2019) and drought-related NBS-NBaS still require significant efforts (Xie and Bulkeley, 2020). In the case of droughts, research needs 694 are more pronounced as studies on NBS-NBaS for slow onset events and their post-occurrence effects are 695 696 still limited (Tuomenvirta et al., 2019). Within some of the pilot sites that include droughts, the latter are mainly addressed as a lack of precipitation (e.g. Mayor et al., 2018). This may be due to their confusion 697 698 with water scarcity which is also often wrongly used as a synonym (GMV et al., 2018). However, this representation constricts the process to precipitation availability, and does not consider the four natures of 699 700 droughts, i.e. meteorological, hydrological, agricultural and socioeconomic. Accordingly, this depiction 701 might lead to an underestimation of drought risks (Vogt et al., 2018 in Tuomenvirta et al. 2019), which in reality are the most complex weather-related disasters due to their widespread cross-sectoral impacts 702 703 (Tuomenvirta et al., 2019). The underestimation of risk will subsequently affect the accuracy of the related 704 solutions. This can be considered as the starting point for drought NBS-NBaS research.

Whether designed for slow or rapid onset climatic events, climate change, the climatic characteristic of the concerned setting, and the frequency and intensity of extreme <u>weather</u> events are very susceptible of reducing the efficiency of NBS-NBaS (Gomez Martin et al., 2019). Climate change also influences the benefits and trade-offs provided by these solutions (Gomez Martin et al., 2019). To consolidate this fact, the following examples are given

Climate characteristics: Small natural water retention features showed considerable potential in the UK,
but had very reduced efficiency in Mediterranean contexts (Douglas et al., 2019). This is due to the
differences of rainfall intensities that require a greater number of retention measures in the Mediterranean
climatic regime (Douglas et al., 2019). In cold climates, the efficiency of edible solutions is questionable
since they won't be able to deliver their service around the year (Wubben et al., 2020) due to plant growth
factors.

Seasonal variations: A spatio-temporal variation in the capacity of NBS-NBaS to provide ecosystem
 services can be observed in several cases (Fletcher et al., 2020). Per example, solutions based on broad
 leaved trees can become relatively inefficient during autumn and winter as they shed their leaves (seasonal

- variation of ecoservices provision). In climates where evapotranspiration fluctuates throughout the seasons,
- the flood volume reduction capacity of green solutions will equally vary (Fletcher et al., 2020). Other NBS-
- NBaS used to reduce incoming solar radiation on buildings will fulfill their functions in summer, but might
- cause increases in heating loads during winter (Canton et al. 2001 *in* Bailly et al., 2019a).

- Extreme weather events: In summer, an unexpected succession of rapid storms may saturate water storage
capacity much faster than the solutions' evapotranspiration rates, hence overpowering the NBS-NBaS
(Fletcher et al., 2020). Similarly, increasing rainfall return periods can reduce the effectiveness of green
roofs, pervious pavements, bio-retention elements and rain gardens (Majidi et al., 2019).

727 3.6.2. Risks of oversimplification

728 In the words of Albert Einstein, "Everything should be made as simple as possible, but not simpler". One 729 of the strongest points of the NBS-NBaS concept is its relative simplicity that makes it widespread and 730 more or less grasped by a large audience. In this vein, O'Sullivan et al. (2020) report that in current NBS literature, a discussion of what forms the N of NBS-NBaS is still missing. According to the same Authors, 731 732 it is unclear if nature only refers to biotic components, or also includes the abiotic factors and their effect 733 on biotic ones. This may be due to the fact that "nature" in NBS-NBaS is defined and interpreted according 734 to the viewer's background or discipline (CER et al., 2018). Most commonly, it seems that actual nature 735 (ecological resources, processes, and feedback loops) is undervalued, with most of the discourse focusing on nature's positive socioeconomic outcomes (O'Sullivan et al., 2020). This narrow focus on benefits 736 737 makes NBS and NBaS utilitarian anthropocentric concepts according to Nature4Cities (CER et al., 2018). While in reality, these concepts encompass complex processes that include different components of the 738 geosphere, hydrosphere, atmosphere and a range of ecosystems (Kumar et al., 2019). 739

740 In terms of NBaS, not only is nature undervalued, but their potential for reducing climate vulnerability and 741 promoting sustainability is also oversold (O'Sullivan et al., 2020). According to Sekulova and Anguelovski 742 (2017) *in* O'Sullivan et al. (2020), nature is romanticized and overestimated to the point where the concepts 743 of NBS-NBaS risk becoming unscientific (O'Sullivan et al., 2020). The same Authors provide a "dose of 744 reality" through a literature discussion of the current perspectives on nature using five references; the most 745 important elements to retain are:

- 746 In terms of NBaS: Nature is being represented as a green injection primarily into cities (Kaika, 2017 in
- 747 O'Sullivan et al. 2020) to help governments make citizens immune to climate change (Esposito, 2013 *in*
- 748 O'Sullivan et al., 2020).

In terms of NBS and NBaS: The drive for green and blue spaces is not environmental nor scientific, but is
rather economic, i.e. growth obsession (Kabisch et al., 2016 *in* O'Sullivan et al. 2020). According to
Sekulova and Anguelovski (2017) *in* O'Sullivan et al. (2020), the environmental angle will almost always
lose at the expense of the socioeconomic goals. This might be due to three reasons:

- i. Emerging literature on urban NBS-NBaS deals mostly with the ecological, socio-cultural and
 economic dimensions (Veerkamp et al., 2018). The integration of "harder science" insights is still
 lacking and can be considered as an important line of research to develop. Hence, one might consider
 that there is a lack of ready-to-apply scientific knowledge (Egusquiza et al., 2017).
- ii. The IUCN labels challenges that NBS-NBaS respond to as societal challenges. This nomenclature
 can be assumed to be logical as these arise from a combination of natural and anthropogenic causes
 (Balzan et al., 2020). However, this indirectly undermines the scientific background of these
 challenges and gives NBS-NBaS a more "practical" nature. This simplification may be beneficial for
 spreading the concepts across different target groups, but risks oversimplifying the underlying science
 behind the challenges, the solutions and the intended outcomes.

iii. Environmental challenges are marked by complexity, uncertainty, large spatio-temporal variability
and often irreversibility (van den Hove, 2000 *in* Fohlmesiter et al., 2019). These elements are
particularly amplified in the case of climate change, hence the increased difficulty of NBaS compared
to NBS. The latter rely largely on the ecosystem service concept in which also insufficient scientific
basis coupled to the inconsideration of nature's intrinsic value are major weak points (Bull et al.,
2016). For NBaS, the same principles apply in addition to the layers of complexity brought about by
the introduction of the already uncertain and complex climate change.

770 If the environmental dimension and science(s) behind NBS-NBaS remain underdeveloped as the concept 771 favors its practical and economic sides, NBS-NBaS risk being lost as buzzwords. To overcome these barriers, significant research efforts are required along with long term visions of resilience (particularly for 772 climate change), instead of short-term research on quality (Bailly et al., 2019a). At this stage, the cross-773 774 sectoral nature of NBS-NBaS might be a helpful factor, yet current efforts are compartmentalized (silo approaches), and the concerned disciplines have very limited interactions with each other (Maksimovic et 775 776 al., 2021). Even when solid knowledge exists, it is often scattered across different disciplines (Bulkeley and 777 Raven, 2018).

778 3.6.3. System complexity

Addressing NBS and to a certain extent NBaS, from the EC's perspective requires a complex interplaybetween definitions, challenges and sought solutions (Morello et al., 2018)..

A solid understanding of nature's and systems' complexity is needed for successfully designing NBS-NBaS
(Schmalzbauer, 2018). This element is currently one the major gaps for upscaling NBS-NBaS (Ruangpan et al., 2020). Once integrated, this understanding can help in complementing the effort of actors of various backgrounds (including ordinary citizens) to ensure the success of any designed/implemented solution.

Whether of small or large scale, the introduction of NBS-NBaS into an already existing (eco)system implies 785 786 the introduction of new nature processes that are often complex and interdependent (Debele et al., 2019). Nearly all the retained projects acknowledge this state and call for adopting complex thinking. The latter is 787 necessary for dealing with the associated uncertainties and risks (Morin 2014 in Bailly et al. 2019b), as it 788 789 also allows to draw attention to the undesirable effects (disservices) that may be brought about (Bailly et 790 al., 2019b). Within the retained projects complexity is addressed in both theoretical and technical angles. 791 The most pronounced aspect of theoretical complexity stems from the targeted environmental challenges, 792 namely climate change and hydrometeorological risk reduction. In terms of CCA, both climate change and adaptation are complex entwined elements. In terms of hydrometeorological risks, the combined 793 794 meteorological and hydrological processes that give rise to a certain event (hazard) create a layer of 795 considerable complexity to consider (Debele et al., 2019). Moreover, hydrometeorological hazards are also 796 capable of occurring simultaneously, in a cascading manner or even additively (Aguzzi et al., 2019). This 797 means that a multitude of factors can interfere hence compounding complexities.

In terms of technical and fundamental knowledge on NBaS, the different projects acknowledge that some 798 799 solutions are more complex than others, and thus require different approaches. For example, reconnecting 800 floodplains (along with the involved hydrological, geomorphological and pedological processes and 801 knowledge) is much more complex than designing allotment gardens (Somarakis et al., 2019). Similarly, some solutions are less difficult to grasp given their relative simplicity and their direct tangible effects. For 802 803 instance, as highlighted in proGIreg, urban farming delivers edible products in a relatively fair amount of 804 time, making it simpler and more lucrative than green roofs that provide less tangible effects, and require extensive expert [scientific and technical knowledge] (Wilk et al., 2020). On the implementation side, 805 806 Saraco et al. (2020b) revealed that during their project, the implementation phase was longer and harder than originally planned. This operational complexity is often a significant hurdle that complicates the 807 808 dialogue between the different concerned actors and can even be a backdrop for a given plan.

- While most of the theoretical and technical difficulties can be resolved through the introduction of moreknowledge, several limits and gaps should be addressed:
- The complexity of the environmental challenges and the solutions themselves calls for significant efforts 811 that are still somewhat underdeveloped, particularly in the domain of assessing the changes brought about 812 by the (re)introduction of "nature" and its processes into a specific ecosystem. Accordingly, there is a need 813 to develop tools that take into consideration the interconnectivity of the natural and newly inserted system 814 (Altamirano et al., 2020). This aspect calls for better understanding of ecological dynamics, in which often 815 816 a particular's system equilibrium comes from the dynamic interactions of factors that result in zero net 817 entropy. While understanding this equilibrium and its components might be a difficult task, it certainly forms an important line of research to develop. 818
- Solutions that target the links between stressors, driving forces and causal factors, while addressing
 adaptation at different spatial and temporal scales are particularly required for addressing multi-hazard
 approaches (i.e. multipurpose NBaS and/or NBaS for DRR).

822 3.6.4. Uncertainty

- Addressing multi-faceted solutions such as NBS-NBaS requires the consideration of complexity,
 redundancy and associated uncertainty particularly through different scales (Egusquiza et al., 2017). A
 chain of uncertainties associated with NBS-NBaS can be observed throughout the different projects:
- The starting point of uncertainties in NBS-NBaS is the dynamic and complex nature of the challenges
 these respond to (Somarakis et al., 2019), namely climate change.
- The second point comes from the unpredictability and uncertainty of the nature (<u>NBaS</u>) "base" itself
 (Somarakis et al., 2019). Linked to that point are two facts: i) under the natural hazard scope, nature is
 perceived by people as an unstable element that might generate catastrophic events, accordingly, the use of
 nature under the form of NBS-NBaS to reduce risks raises some skepticism (Chou, 2016 *in* Han and
 Kuhlicke, 2019). ii) NBS-NBaS build on ecosystem functions and services, which in turn are dynamic,
 uncertain and evolve over time often in non-linear manners (Somarakis et al., 2019).
- 834 - The use of NBS as tools for CCA is still relatively recent and not very widespread due to underlying conservationism (Kuban et al., 2019). The latter might be due to lack of knowledge that creates a fear of 835 836 the unknown (Solheim et al., 2021) that subsequently propagates across the various elements of the NBS-837 NBaS chain (design, implementation, operationalization, etc.). According to the NAIAD and UNaLab projects, as NBS-NBaS are still perceived as innovations, their conception as uncertain elements is a source 838 839 of risk (Altamirano et al., 2020; Stahlbrost et al., 2018). In this vein, upscaling and mainstreaming NBS-NBaS become challenged by: i) the difficulty of capturing the value of NBS-NBaS, ii) the lack of 840 841 understanding of long-term benefits and iii) the uncertainties due to the disconnection between short-term actions and long-term goals (Perrin, 2018). 842
- Adaptation is often challenged by the absence of decisive metrics. Therefore, measuring adaptation is an
 uncertainty barrier to overcome for NBaS. To this end, when adaptation is questionably calculated, NBaS
 are inaccurately designed, and uncertainties for quantifying climate resilience increase since the latter is the
 sum of CCA and CCM actions.

847 3.6.5. The scale quandary

Most H2020 NBaS projects are demonstration projects that often target small or specific pilot scales (except for OPERANDUM, PHUSICOS, RECONECT, FutureMARES and PONDERFUL). With the global spread of NBS around the world, European pilot-sites and cluster projects intervention are making Europe stand out as the world NBS leader (CLEVER Cities, 2021). Per example, living labs are much addressed throughout different projects, namely those that concern the urban medium (Wilk et al., 2020). In these 853 units, economic/technological methods and concepts are developed and put to the test in a small real-life 854 context (Wilk et al., 2020). It is believed that the diversity of size and scales of the pilot sites facilitates the 855 extrapolation of findings to bigger scales having similar climatic properties (Boskovic et al., 2021). However, despite their importance, demonstration projects only generate applied and site-specific 856 knowledge (Xie et al., 2020) and are often practical variations of earlier research (Strout et al., 2021). This 857 recurrently makes of them NBS-NBaS awareness raising projects (Altamirano et al., 2020), rather than 858 knowledge generating elements. This might be due to the site-specific nature of NBS-NBaS that 859 complicates the generation or communication of "harder" aspects of knowledge (Xie et al., 2020), or to the 860 861 oversimplification of the concept as discussed in the previous section.

862 Regardless of the type of knowledge generated, the narrow focus on specific scales (mostly pilot site interventions that do not extend beyond a plot, district or neighborhood scale or plot, tributary, sub-basin) 863 makes the identified limitations, achieved successes and the methods developed not necessarily applicable 864 or replicable at both finer or larger scales (Somarakis et al., 2019). In this vein, upscaling to larger scales 865 866 (i.e. greater than pilot sites) is a significant challenge for scientists and researchers, as the knowledge and methods utilized in pilot sites may not be applicable at larger scales (von Wirth et al., 2019 in Schmalzbauer, 867 2018). In addition, the requirements for much more resources and the buy-in of powerful actors add another 868 869 layer of difficulty.

Moreover, the scales used by the research community do not always match those of planners (Knaus and 870 871 Haase, 2020). This scale mismatch poses direct barriers to knowledge transfer and researcher-practitioner 872 contact (Knaus and Haase, 2020). While the pilot scale approach is very important, NBS should be 873 considered beyond their local effects, must be connected and should have a multi-scalar nature (Bailly et 874 al., 2019a), i.e. they should be studied across and through different scales. To that end, there is a pronounced 875 gap in the amount of research on small scale (e.g. urban) and large scale (e.g. catchment or regional) NBS (Ruangpan et al., 2020). Currently, the implementation of NBS-NBaS at large scales is limited, and is rather 876 restricted to pilot site interventions of limited sizes (Altamirano et al., 2020). The complexity of larger 877 878 systems might be a valid underlying reason, however this disconnection between scales is a significant 879 hurdle for upscaling (Ruangpan et al., 2020). The lack of experience in large scale ecosystem restoration 880 practices (Banwart et al., 2019, 2018) may also be a contributing factor.

In the case of NBS-NBaS for DRR, particularly hydrometeorological hazard reduction, implementation is 881 often at small-scale, and hence with a negligible effect on large hazards (Kumar et al., 2019). Expecting 882 from a single NBaS to reduce risks and damage costs, as well as provide a quantum leap in resilience might 883 be too ambitious. Per example, punctual/local stormwater management solutions aren't as effective as 884 watershed scale NBS-NBaS that buffer peak runoff and flooding risks in the whole spatial unit including 885 the target area (Somarakis et al., 2019). However, relevant evidence and knowledge are still somewhat 886 887 limited when NBS-NBaS are part of a larger hydrological system (Ruangpan et al., 2020 in Solheim et al., 2021; Turconi et al., 2020; van Soesbergen and Mulligan, 2018). The same applies for watershed scale 888 hybrid solutions that contain both small size or large sized NBS-NBaS (Watkin et al., 2019). As a result of 889 these factors, most risk assessments target small scales (local to regional approaches) often leaving out the 890 larger matrix (Renaud et al., 2019). Consequently, large scale NBS for hydrometeorological risk reduction 891 are left out of the picture as the spatial unit of assessment disregards them. Therefore, these solutions are 892 893 still in serious need for further studies particularly in European reference frameworks (Vojinovic et al., 894 2019). This knowledge gap can be considered as a major bottleneck for holistic risk management and 895 resilience plans where large scale NBS-NBaS interventions are often needed (Somarakis et al., 2019).

In the case of NBS for climate resilience (i.e. NBaS and NBS for CCM), the difference of scales is also a
complex factor. Generally, these type of solutions call for two scales: for mitigation, solutions are sought
at macro scales while adaptation solutions target the meso and micro scales (CAR et al., 2017; GMV et al.,
However, other Authors believe the opposite and stress that adaptation plans and actions should

900 target the landscape or wider scales to account for all the interactions of the concerned ecosystems (Kapos

901 et al. (2019) in Altamirano et al. 2020). Yet different climatic challenges also require different scales and 902 that itself is an additional barrier. For instance, NBaS for UHI reduction require a city scale approach, 903 pluvial flooding requires an urban zone scale intervention, while river flooding requires a watershed scale approach (Somarakis et al., 2019). Arguably, evidence of small scale interventions is more or less 904 established, however similarly to NBS for DRR, evidence of efficiency is particularly lacking at large scales 905 (landscape or watershed). As the concerned challenges are often multi-scalar, the difficulty of measuring 906 907 the solutions' multi-benefits and efficiency increases (Davis et al., 2018). To this end, sufficient best 908 practices in different settings are still lacking (Knoblauch et al., 2019) and significant research efforts are 909 still needed.

910 3.6.6. Measuring progress and monitoring NBaS

911 The efficiency and the success of a solution are generally measured after its implementation by determining the changes between its pre and post existence phases. However, a solid base on NBS evidence is still 912 913 lacking in scientific literature (Douglas et al., 2019). NBaS also still lack well-established proof of their 914 effectiveness for CCA/CCM, especially in relation to the achievement of their set targets (CAR et al., 2019). Accordingly, NBaS are still in a state of unknown performance (CAR et al., 2019). In this vein, research 915 efforts yielded many evidence of climate change, yet no conclusive evidence of NBS-NBaS benefits, 916 performance and functionalities is established (Bailly et al., 2019a). The same also applies in the domain 917 of NBS-NBaS for hydrometeorological hazards (Debele et al., 2019). 918

In response to this state, current research on NBS is focusing on finding/building indicators for providing conclusive evidence on the efficiency of these solutions (Collier, 2021). However, this line of research is still somewhat embryonic, and further efforts are needed (Somarakis et al., 2019). Under the H2020 projects, a multitude of monitoring and assessment frameworks, and a plethora of indicators are used and presented (namely MAES, UNaLab, NATURVATION, EKLIPSE and others). Most projects use the EKLIPSE framework (Raymond et al., 2017), while others develop their own assessment frameworks such as the projects listed in Table A (refer to Supplementary Material 1).

926 However, there still isn't a commonly accepted or uniform monitoring and evaluation framework 927 (Schmalzbauer, 2018). Even when monitoring occurs, the length of monitoring period is often short or is characterized by a low frequency. This may be due to the fact that an unknown amount of time is needed 928 for a NBS-NBaS to become fully effective (Somarakis et al., 2019). According to Kuban et al. (2019), the 929 930 difference of time scales between the short to medium NBS-NBaS interventions, and the long time needed to unravel their effects makes this type of analysis difficult. In this sense, Garcia Perez et al. (2018) in the 931 932 CLEVER Cities project recommend that monitoring and evaluation should go along with the maturity of 933 the solution, i.e. at least five years post-implementation. Conversely, Holscher et al. (2019) recommend the integration of monitoring and evaluation as early as the design phase, since the whole NBS-NBaS chain is 934 loaded with underlying assumptions and uncertainties. Accordingly, the NBS-NBaS monitoring and 935 evaluation framework should be progressive and continuous, to the point where outcome data following 936 937 implementation can become baseline data for the future implementation of other solutions. Following this 938 logic, NBS-NBaS should be gradually introduced to have a sufficient time period for a detailed and careful assessment of their efficiency (Albert et al., 2017). This gives a certain degree of flexibility for refinement 939 940 throughout the process (Albert et al., 2017) and ensures the gradual success of the solution. Then again, the question of measuring success is raised by the UNaLab project: what are the acceptable thresholds to 941 consider the solution as a success and at what scale (Wendling et al., 2019)? This last point is particularly 942 943 important since the most significant difficulty for designing a monitoring scheme is to determine the scale of impact (Wendling et al., 2019). Accordingly, the following questions are also raised: will the 944 implemented NBS-NBaS have benefits beyond its location? Is it part of a bigger NBS-NBaS network? If 945 so, how can it be individually assessed within the larger matrix? 946

All of the retained projects contained different sets of Key Performance Indicators (KPIs) for monitoringand evaluating their implemented solutions. Some projects also address monitoring and evaluation through

949 a modeling and/or impact assessment approaches. The former surpasses the latter with it predictive 950 capacities (Bulkeley and Raven, 2018) that can provide better insights, namely by comparing pre, peri and 951 post NBaS phases. They can also serve to project future changes in scenarios (NBaS expansion, climate 952 change, etc.). However, it is crucial to acknowledge data and model limitations as even the best available data can hold large uncertainties at different scales (Burke et al., 2018). For instance, engineering models 953 are not very suitable for tackling NBS-NBaS interventions as the latter are of highly distributed nature 954 955 (Burke et al., 2018). Modelling can also be a source of skepticism since it is based on assumptions that are 956 not necessarily justifiable in real-life cases (Olsson and Andersson, 2006 in Kumar et al. 2019). In addition, 957 over ambition in modeling must be avoided as in some cases, simulations are run on the basis of scenarios that may never occur (e.g. 100% case of green roofs in an urban setting). 958

959 NBaS aim to address climatic challenges through specific actions. In turn, each action has an associated set of awaited impacts that also requires specific array of quantitative indicators related to climate resilience 960 (Bailly et al., 2019b). To that end, there are still questions concerning: i) the efficiency of NBS-NBaS under 961 962 different climatic situations, and ii) how NBS-NBaS accelerate the adaptability of a context (Debele et al., 2019). As NBS-NBaS require time to mature and become fully effective, the delivery of their co-benefits 963 can be gradually produced at different time steps (Giordano et al., 2020 in Gomez Martin et al. 2019). A 964 965 certain co-benefit can decrease the delivery of another, meaning that the overall effectiveness of NBS-NBaS will also be influenced (Gomez Martin et al., 2019). This issue should also be monitored as the 966 success of a NBS-NBaS not only depends on the delivery of co-benefits, but also on producing a balance 967 between them (Gomez Martin et al., 2019). 968

969 The debate on qualitative versus quantitative assessment is also polarized. While quantitative indicators are 970 needed to provide solid numerical insights, qualitative indicators are equally needed to provide context-971 specific information that often characterize NBS-NBaS (Da Silva et al., 2020). Even if several indicators of quantitative nature have been built, there's still a call in literature for more robust numerical frameworks 972 to assess the performance and benefits of existing or newly installed NBS (Watkin et al., 2019). In their 973 974 own right, defining qualitative indicators - e.g. measuring well-being - is a challenge, since these can be 975 subjectively interpreted and lack a straightforward/consistent methodology (Da Silva et al., 2020). This limitation poses subsequent difficulties for the evaluation of these solutions' efficiency, values and benefits 976 (Ruangpan et al., 2020). Despite the various efforts of some projects for developing a common indicator 977 978 framework (e.g. ThinkNature), measuring intangible values is still a considerable hurdle to overcome 979 (Schmalzbauer, 2018). For this purpose, significant multi and transdisciplinary approaches are needed (European Commission, 2021b). However, according to Basta (2021), none of their examined H2020 980 981 projects up until 2019 implemented frameworks for evaluating the credibility, relevance and effectiveness of the knowledge generated or reported during their research phases. This means that there weren't any 982 uses of systematic monitoring and evaluation for documenting transdisciplinary research or methods (Basta, 983 984 2021).

985 *3.6.7. On resilience in the H2020 projects*

As can be noticed, the term resilience is present throughout the different sections of the manuscript. It is often associated with the process of adaptation. However, the resilience-adaptation nexus is quite polarizing as both can promote and demote each other at the same time (Nelson, 2011). Under the climate change scope, both concepts show pronounced differences (Leggett, 2021). Generally, climate change response strategies often require resilience OR adaptation (Wong-Parodi et al., 2015), i.e. a sort of separation/competition between the two concepts.

Adaptation is mainly sought for coping with the implications of climate change, while resilience is sought for developing the capacity of withstanding the threat. As such, adaptation is a process, while resilience is a capacity (Leggett, 2021). In the IPCCC's definition of resilience, a great deal of importance is given to the amount of change that a system can withstand, hence relating resilience to coping ranges (Levina and Tirpak, 2006). 997 Arguably, adaptation helps a system to absorb shocks while resilience helps the system to do so and resume 998 its functioning (Der Sarkissian et al., 2021). However, no consensus on the resilience-adaptation nexus 999 exists. This could be due to the fact that adaptation and resilience have emerged from different research 1000 disciplines (Nelson et al., 2007) and under dissimilar contexts (Nelson, 2011). Nonetheless, one might argue 1001 that resilience is needed for managing systems in a flexible and adaptive way. Under this context, resilience 1002 can be considered as a mean to broaden the reach of adaptation, hence the intersection zone between both 1003 concepts (Nelson et al., 2007).

1004 As climate change is the main scope of the retained projects, climate resilience is addressed as the sum of 1005 CCM and CCA. The former (i.e. CCM), is usually better quantified since it is related to the reduction of emissions and carbon storage or removal. Such indicators are well-established throughout the different 1006 projects with many metrics for carbon storage/removal capacities of soils and biomass (e.g. UNaLab). 1007 1008 Conversely, the lack of adaptation targets, metrics, and indicators hinders accurate resilience quantification efforts. Moreover, under the NBS-NBaS scope, resilience is often delivered through ecosystem services. 1009 1010 As mentioned in previous sections, the difficulty of quantifying ecosystem services adds another layer of 1011 complexity. Certainly, these disparities complicate regional comparisons for evaluating the quality of NBS-NBaS beyond the pilot sites they exist in. The site-specific nature of these solutions also prevents cross-1012 1013 comparisons. Consequently, the evaluation of NBS-NBaS currently does not extend beyond pilot sites.

1014

1015 In relation to adaptation pathways, these were created for efficient policymaking in the face of future uncertainties. Accordingly, these ensure iterative and flexible approaches that accommodate for climate 1016 change and its uncertainties. By aggregating adaptation options, assessing their effectiveness and 1017 sequencing them in the form of pathways, Zorita et al. (2021) indicated that the use of adaptation pathways 1018 1019 is an efficient method for city or sector levels. Nonetheless, do not extend to higher scales. Therefore, the 1020 connection of adaptation pathways to resilience trajectories in a multi-scalar feature-space is yet to be 1021 understood. These observations converge with the recommendations of Cai et al. (2017) for promoting 1022 further research on multi-scalar resilience.

1023

1024 *3.6.8. The other side of the coin: disservices*

1025 One of the main advantages of the NBS framework is that it acknowledges the existence of disservices 1026 (Schaubroeck, 2017). However, it isn't until recently that disservices became well discussed in NBS 1027 literature. In terms of NBaS, one of the most perceivable risks is climate gentrification (Kiss et al., 2019). Almost all of the retained projects acknowledge their existence and incorporate some related types of 1028 analysis during their design or planning phases. However, only accounting for disservices is not enough. 1029 There is an equal need to account for trade-offs particularly when one ecosystem service decreases due to 1030 an increase of another (Bailly et al., 2019a). In that sense, NBS-NBaS may lead to negative consequences 1031 on ecosystemic balance (Banwart et al., 2019). It is therefore important to acknowledge that any NBS-1032 1033 NBaS can have unexpected or unplanned negative outcomes, for despite their importance, NBS and NBaS 1034 consume natural resources while they exist (Somarakis et al., 2019). Therefore, one should not assume that the NBS-NBaS intervention will surely work (Burke et al., 2018). That is why the risk of failure should 1035 1036 always be accounted for. Therefore three scenarios are recommended to be expected. The first is a case 1037 where everything occurs as planned, the second is a best scenario where all expected elements are achieved 1038 to the maximum, and the third is a critical scenario where failure is expected.

However, according to UNaLab, disservices and risks are often outweighed by the long-term benefits of NBS-NBaS (Hawxwell et al., 2018). Nonetheless, this does not mean that disservices are to be treated lightly as in some cases these can have serious consequences. For instance, with a changing climate, increasing the extent of water bodies might be a serious proliferation factor for water-borne diseases (particularly in tropical or equatorial settings). Such considerations need to be made according to the reigning climatic regimes. To this end, disregarding disservices during early analysis is a significant threat that can amplify risks and lead to efforts in vain (Bailly et al., 2019a).

1046 4. Conclusion

1047 In this paper, a thorough analysis of NBaS projects issued from the H2020 program was performed. The 1048 purpose of this study was to build a scientific state-of-the-art on current knowledge and research needs from 1049 the analysis of European contributions. For this purpose, 21 out of the retained 27 projects had deliverables at the time of this study and thus formed its basis. From a total number of 173 deliverables, 137 were 1050 retained and analyzed with respect to the scope of this study. In this regard, only environmental and 1051 biophysical elements were included as this study was concerned more with the fundamental and theoretical 1052 1053 basis of the concept. Nonetheless, this does not take away any degree of importance from the concept's 1054 technical, political and socioeconomic aspects. In this vein, one of the main challenges for this study was to synthesize and compile knowledge from very different sources as a result of the projects' diverse 1055 background (different nature and disciplines). This last element prevented drawing clear parallels between 1056 1057 projects and directly comparing their outcomes even within the same study areas. The different targeted 1058 contexts, climatic settings, and socioecological characteristics also added another layer of complexity for 1059 direct comparisons. To account for this factor, an extensive review and in-depth analysis were performed 1060 to connect the different dots and draw a clear line of work.

1061 The Authors acknowledge the partial descriptive nature of the results. However, the aims of this paper was 1062 to present a timely inventory of H2020 efforts with a focus on the EU's progress, contribution, and status. 1063 It can be considered more or less as a roadmap of what has been accomplished/found till now (state-of-the-1064 art), with a contribution to develop lines of work that were proposed based on identified limitations and 1065 gaps. On this basis, the paper can be listed as an effort to provide a comprehensive roadmap for studying 1066 the ongoing and progressive transition from NBS to NBaS.

1067 While many projects generate/generated substantial amount of knowledge, most of their approaches are 1068 still demonstration or pilot-site interventions. Accordingly, these often take the form of awareness-raising 1069 elements rather than knowledge generators. As mentioned previously, the findings of this paper are not 1070 undebatable as the sample choice and size may induce certain flaws. However, the flaw margin was reduced 1071 as much as possible by filtering the documents thoroughly and by avoiding assumptions. In what follows 1072 several relevant recommendations are given:

i. Extending interests beyond the urban ecosystem

1074 The interest of the EC's H2020 program in the urban realm is justifiable. Yet, a deeper approach to other 1075 ecosystems is much needed. The relative dominance of the urban medium makes most of the knowledge 1076 generated from the H2020 projects related to these settings. Accordingly, a large proportion of the generated 1077 knowledge and methods cannot be necessarily generalized to other media. In the same vein, the biased 1078 focus on urban contexts complicates the identification of NBS-NBaS gaps in other ecosystems. In a given 1079 way, the current interest in ecosystems is constraining NBS to cities, hence the risks of missing out on their 1080 potential in other systems.

1081 This is particularly the case of mountainous, forested and marine and coastal environments. While forests 1082 are very appreciated as NBS-NBaS, they are rarely targeted as a sensitive media to climate change. In its 1083 own right, the mountainous environment is significantly underrepresented despite its importance and 1084 relative widespread coverage in Europe. The marine and coastal realms are also underrepresented as both 1085 a medium and a source of solutions.

1086 ii. Enhancing knowledge on nature (N) in NBS and NBaS

European findings underlined the need to focus more science on the N (nature) behind NBS and NBaS. For this purpose, scientific and physical methods are needed to better understand the interaction of nature both with and within the implemented or planned NBS-NBaS. However, this does not come as an alternative to the concept's practical and socioeconomic nature, but rather as supplement. The rationale behind this logic is to have a holistic framework that balances between all the theoretical and fundamental components of 1092 NBS and NBaS. This is due to the fact that the introduction of these solutions into ecosystems causes the 1093 entry of new systems along with their processes. Yet the investigation of these interactions and their 1094 cascading effects is still somewhat limited. This gap could be on the most pronounced challenges for 1095 upscaling and outscaling NBS-NBaS as well as for unlocking their full potential.

1096 iii. Exploring and developing several lines of research work

1097 Cross-cultural analysis in a global sense, does not appear in the H2020 environment. While community-1098 based actions and civil society participation are well accounted for, an analysis of how cultural knowledge 1099 reconcile with natural ecology and sustainability is not always present. Embedding this approach into a global scale environment (beyond a Europe-focused approach) might be worthwhile considering. The 1100 1101 rationale behind this proposition is that deeper insights on cross-cultural aspects can leverage the use of NBS-NBaS by providing inputs to the science-practice-policy sphere. Accordingly, the co-design, co-1102 implementation and co-production of solutions are ensured. In this vein, the ARTISAN project, through its 1103 1104 analysis of international, regional (European) and national (French) efforts is aiming to position each scale 1105 with respect to other. With the advances of the project, more multi-scalar insights on NBS-NBaS are 1106 expected.

1107 In terms of European outlooks, according to Davies et al. (2021), the EU's intention to continue investments in NBS is still increasing. The same Authors indicated that the recently launched FP9 Horizon Europe 1108 1109 program (2021-2027) will aim to integrate NBS into areas such as health, bioeconomy and food systems 1110 with a particular emphasis on climate change. Accordingly, the extension beyond urban ecosystems is 1111 starting to appear. While climate change remains a central challenge under the Horizon program, the transition from NBS to NBaS can still be considered as ongoing. In this vein, studying the intersection 1112 1113 between this paper's listed projects (ongoing ones), and those launched under FP9 could be an interesting platform to consider. According to Davies et al. (2021), both in the EU and beyond, the discourse on NBS-1114 NBaS should shift from their representation as "products" to become considered as a "process". In this 1115 1116 vein, several perspectives can be proposed:

1117 1. It is crucial to understand if NBS-NBaS are being currently designed to withstand weather change and/or
1118 climate change. In a second step, it is important to determine if these solutions be capable of overpassing
1119 weather change to then withstand climate change.

1120 2. The labelling of the NBS-NBaS challenges as societal makes the concept tip towards more practice 1121 centered orientations rather than knowledge generation or science-focused priorities. Moreover, under any
 1122 context, the definition of the societal/environmental challenge to be targeted by NBS-NBaS should be an
 1123 ongoing process

1124 3. While oversimplification might be attended to by increasing the integration of hard sciences, a solid 1125 understanding of the complexity of natural systems and their processes is needed. However, a careful 1126 balance between simplification and complication should always be kept to avoid losing NBaS. The aim of 1127 this approach is not to make NBS-NBaS limited to experts as one of the concept's strongest points is its ability to create a shared vision/language and implicate a broad societal commitment to the design and 1128 1129 implementation of nature. Yet, oversimplifying the concept can make it a simple buzzword, while overcomplicating it can make it lose its acceptance/popularity among the different groups that are needed 1130 1131 to leverage these solutions.

4. The role of uncertainties in NBS and NBaS should be better accommodated and explored through further
research (Bailly et al., 2019b; Han and Kuhlicke, 2019; Van der Jagt et al., 2020). The same can be said for
uncertainties and trade-offs (Kumar et al., 2019). While these are developing lines of work, their current
acknowledgment under all projects reflects the attainment of an ample awareness level.

5. For the implementation of system scale NBS-NBaS, a leap beyond conservationism is needed. Studying
a mosaic of existing projects as a large scale NBS-NBaS approach through scale transitions may be a good

- start. To this end, large scale NBS-NBaS (when existent) should be treated as aggregated multi-scale small
- NBS-NBaS interventions to attend to their implementation, monitoring and benefit quantification angles.
 It is important to consider that large scales (e.g. watersheds) cover a mosaic of ecosystems. That means that
- different responses to various stimuli (in this study's case climate change) are to be expected. For this
- 1141 different responses to various stimul (in this study's case chinate change) are to be expected. For this 1142 purpose, understanding tipping points and thresholds is a must. However, this task is quite complicated and
- 1142 purpose, understanding upping points and unesholds is a mus
 - 6. For attending to large scale NBS-NBaS (upscaling), as indicators cannot be simply added up or extrapolated, connecting the different solutions scattered throughout a large area might be a better idea than aggregating small disconnected solutions. The connection between solutions implies a connection of ecosystems, which in turn creates various ecotones. This ecotone effect allows a maximization of individual efficiencies and multiplies benefits (UNaLab, 2019). To the knowledge of the Authors, tapping the potential of NBS-NBaS ecotones hasn't been dealt with yet in literature, neither have their transitions through different scales.
 - 1151 7. Understanding how NBS-NBaS utilize natural resources and nature during their existence is a relatively1152 understudied and unexplored line of work.
 - 8. The implementation of new NBS-NBaS in sites may lead to soil disturbance (Connop et al., 2020).
 Accounting for soil as both an ecosystem and a potent solution should be further developed namely for
 flood storage capacities and climate change regulation.
 - 9. Within the urban realm, it is crucial to acknowledge that the city will continue to develop throughout the existence of the solutions. Therefore, the parallel evolution of both ecosystems should be further studied in order to determine how both influence each other and to orient proper decision making. Tracking the parallel evolution (current and future) of both ecosystems and solutions is still a relatively untapped domain that deserves further attention.
 - 10. As one NBaS is not sufficient to attend to CCA, the multiplicity of solutions will deliver more
 pronounced effects since these power the necessary interconnections (Bailly et al., 2019b). However, to the
 knowledge of the Authors, measuring the climatic connectivity effect of NBaS is still an untapped domain.
 - 11. Understanding ecosystem tipping points and ecological thresholds is a must. Currently, very few to noefforts focus on these central elements.
 - 1166 12. An understanding of the supply and demand of ecosystems and their services in complex1167 multidimensional contexts is still limited.
 - 1168 13. A systematic approach to understand how the different systems, i.e. ecosystem-NBS-NBaS, interact
 with and influence each other is still limited. Hence the need to provide a more inclusive and holistic
 evaluation framework for properly understanding combined benefits, co-benefits and disservices

1171 Acknowledgments

- This work was realized under the Life ARTISAN (Achieving Resiliency by Triggering Implementation of
 nature-based Solutions for climate Adaptation at a National scale) LIFE18 IPC/FR/000007 project. It was
- also supported by the Academic Chair "Hydrology for Resilient Cities", a partnership between the Écoledes Ponts ParisTech and Veolia group.
