Mise en évidence des rejets urbains de biocides à travers la contamination des eaux de surface de l'agglomération parisienne

Urban discharges of biocides evidenced by surface water contamination in the Paris conurbation

1. Introduction

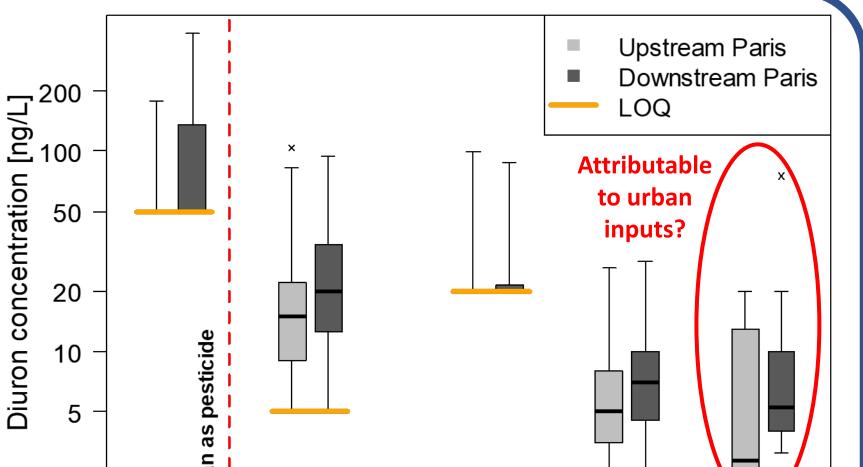

The great expectations held for DDT have been realized. During 1946, exhaustive scientific tests have shown that, when properly used, DDT kills a host of destructive insect pests, and is a henefactor of all humanity.

Etymologically, **biocidal substances** refer to a wide variety of compounds designed or used to "kill life". While 75 years ago, DDT was presented as "a benefactor of all humanity" (Figure 1), the widespread use of biocidal substances is now recognized as a major environmental threat. Over the last decades, huge emphasis has been placed on **pesticides** and their impact on the quality of aquatic environments: various mitigation actions have been implemented, including the ban or substitution of certain compounds, and the overall reduction of the quantities used.

The example of diuron (Figure 2) shows that the ban on this substance as a pesticide has led to a tenfold reduction in its concentrations in the Seine River within 10 years. Nevertheless, diuron concentrations stabilized at a non-negligible background level, which raises concerns about the **contribution of urban areas** as additional sources of biocides^{1,2}.

Various approaches have been implemented to gain insight into the urban emissions and pathways of biocides, such as pilotscale leaching experiments³, *in situ* sampling or elution experiments at small-scale infrastructures⁴, stormwater sampling at the outlet of different catchments⁵, WWTP influent sampling under different weather conditions⁶... As a complementary approach, the present assessment consists of targeting the main receiving environment at the scale of the Paris megacity, *viz.* the Marne and Seine Rivers, in order to collect some evidence of the urban contribution to surface water contamination.

2. Materials & Methods

Sampling of surface waters

- Alfortville (upstream, Seine River)
- S^t-Maurice (upstream, Marne River)
- Conflans-S^{te}-Honorine (downstream)
- Wastewater Treatment Plant: Seine centre

Sampling of urban effluents

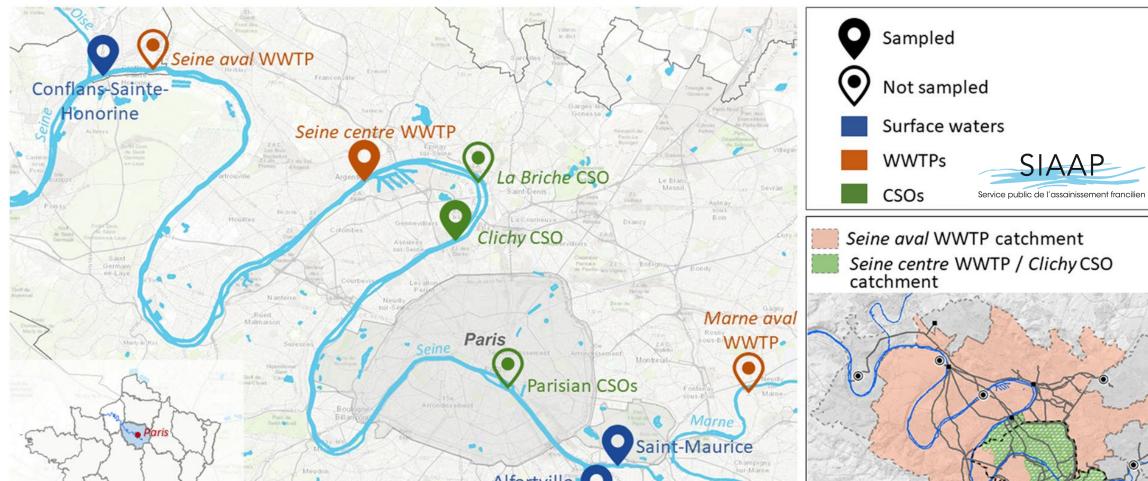

Combined Sewer Overflow: Clichy

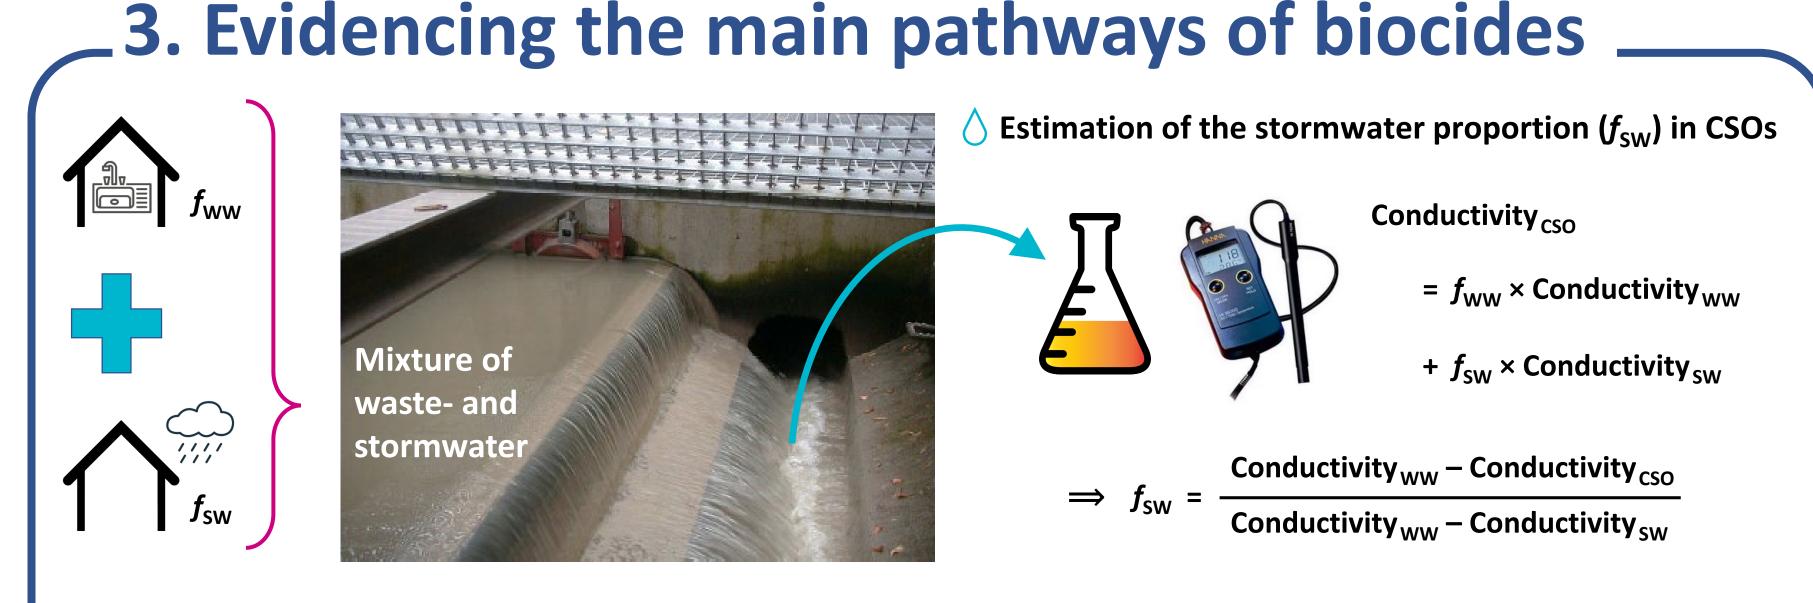

in collaboration with SIAAP

Biocide analysis (HPLC-MS/MS)

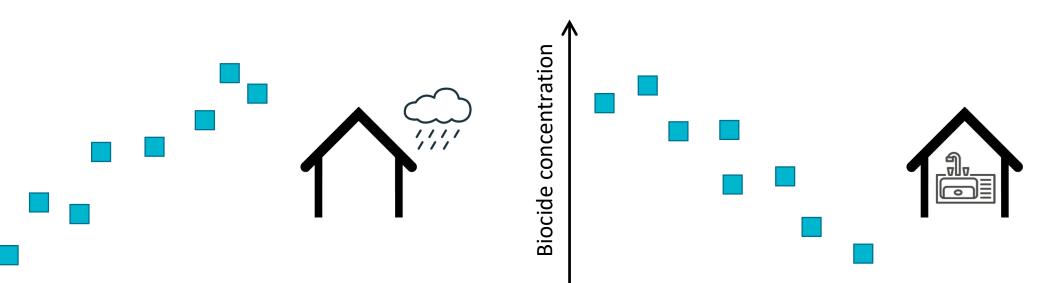

Focus on biocides with different uses in urban areas:

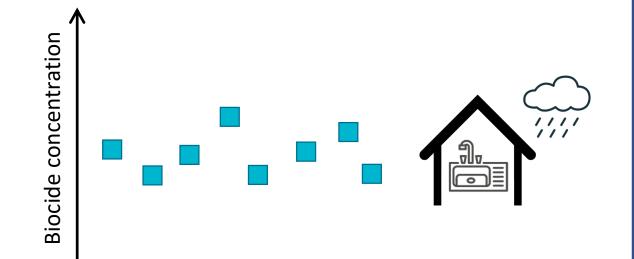

- Compounds mainly used in household products: isothiazolinones (methyl-, benz-, and octylisothiazolinone – MIT, BIT, and OIT, respectively)
- Compounds with mostly outdoor uses: diuron, isoproturon, terbutryn
- Widespread compounds: benzalkonium chlorides (BZK), thiabendazole

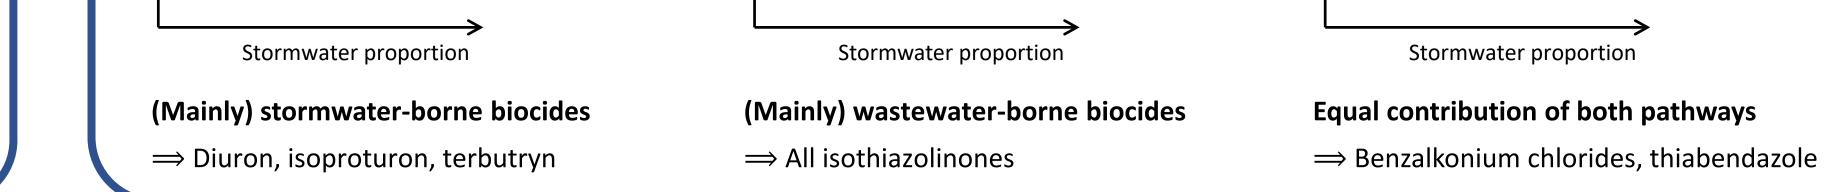

Relationship between f_{sw} and biocide concentrations? Three possible patterns (A mock data):

4. Influence of wet weather.

▲ Figure 3 – Presentation of the study area (~ 6 000 000 inhabitants on approximately 1000 km²) with the major

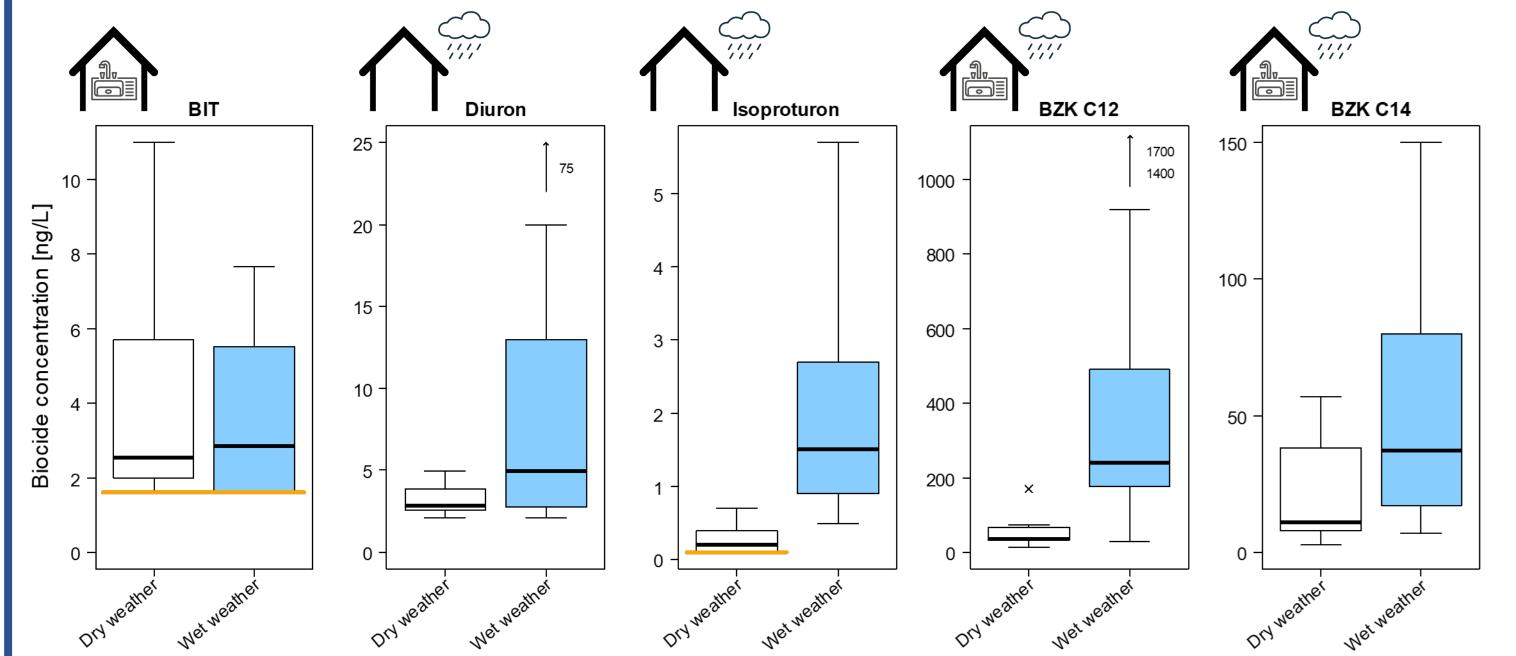

Seine Valenton

urban sources of biocides, as well as the different sampling locations.

From one campaign to another, some biocides showed concentrations spanning more than one order of magnitude in surface waters (*e.g.*, from 10 ng/L to 1.7 μ g/L for benzalkonium C12). So as to better understand this variability, samples were categorized according to the weather conditions during the four days preceding the sampling campaigns (Figure 4).

The substances proven to be stormwater-borne, or with an equivalent contribution of pathways, presented significantly **higher concentrations in surface waters during/after a rainy period** than in dry weather, showing the impact of stormwater discharges. Contrariwise, for isothiazolinones (mainly wastewater-borne), no difference was visible in surface waters between the two weather conditions.

5. Upstream-downstream differences

× 3 sampling locations and N campaigns

Upstream campaigns were synchronized, allowing for summation

For several biocides, a significant increase was evidenced between up- and downstream mass loads. Figure 5 indicates a 95% confidence interval for the shift between the two distributions, which for BIT (wastewater-borne) included the estimated average load in WWTP effluents (~ 50 g/day, Paijens *et al.*, 2021). This result by no means represents a "mass balance closure" but supports the idea that wastewater (even after treatment) may contribute to river contamination by biocides.

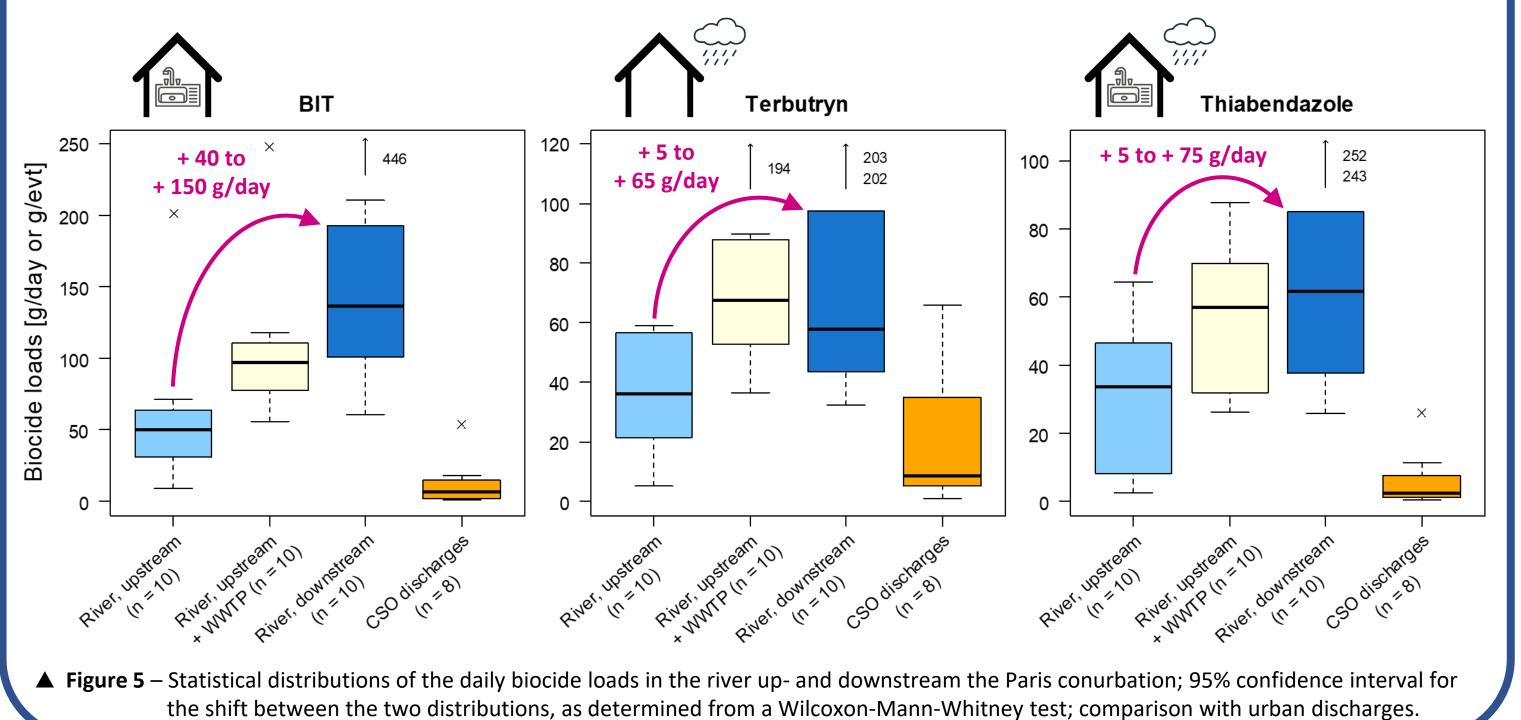

Figure 4 – Statistical distributions of different biocide concentrations (all sampling points merged) as a function of the weather conditions during the 4 days preceding the sampling campaigns. The orange line indicates the limit of quantification.
